**Engine Management System IC**

**1 Overview**
**Features**

- Voltage pre-regulator
- Integrated 5V regulator
- 2 integrated 5V trackers
- Standby regulator
- Separate internal supply
- Voltage monitoring
- High speed CAN interface with wake up by bus
- LIN interface with high speed mode for K-Line operation
- Variable reluctance sensor interface
- Micro Second Channel interface (MSC) with low voltage differential signal (LVDS) inputs pads for low EME
- SPI and direct control inputs for high flexibility
- Main relay driver
- Ignition Key detection with key off delay output
- Wake up input
- Engine off timer
- 4 low side power stages especially to drive injectors ( $R_{on}=550m\Omega$ ) with enable input
- 3 low side power stages ( $R_{on}=350m\Omega$ )
- 6 push pull stages for driving on-board MOSFET with drain feedback
- 7 low side power stages especially to drive relays ( $R_{on}=1.5\Omega$ ), one with delayed switch off functionality
- 4 half bridge stages for high flexibility, one with delayed switch off functionality
- 4 push pull stages for driving on- and off- board IGBT with back supply suppression and high voltage capability
- Open-load, short-to-GND and short-to-BAT diagnostic
- Over temperature and short-to-BAT protection
- Monitoring watchdog module
- Green Product (RoHS compliant)
- AEC Qualified

**LQFP-100**
**Description**

The device is a U-Chip suitable for automotive engine management systems. It contains the basic functionality to supply the micro controller and the ECU, establish the communication on- and off- board and drive EMS typical actuators. Furthermore it controls the main relay driver.

Type	Package	Marking
TLE8888-1QK	LQFP-100	TLE8888-1QK
TLE8888QK	LQFP-100	TLE8888QK
TLE8888-2QK	LQFP-100	TLE8888-2QK

**Device Variants TLE8888QK and TLE8888-2QK**

The device variants TLE8888QK and TLE8888-2QK differ from the main version TLE8888-1QK in the watchdog functionality.

The TLE8888QK has a fixed set of parameter for the watchdog (see datasheet addendum "TLE8888QK - Addendum").

For the TLE8888-2QK the watchdog function is disabled (see datasheet addendum "TLE8888-2QK - Addendum").

Only the main version TLE8888-1QK is described in this datasheet.

For order conditions please contact the nearest Infineon Technologies office.

## 1.1 Abbreviations

**Table 1** Abbreviations

<b>Symbol</b>	<b>Explanation</b>
MSC	Micro second channel
SPI	Serial peripheral interface
LVDS	Low voltage differential signal
EME	Electromagnetic emission
EMI	Electromagnetic interference
LIN	Local interconnect network
HS CAN	High speed controller area network

## 2 Block Diagram

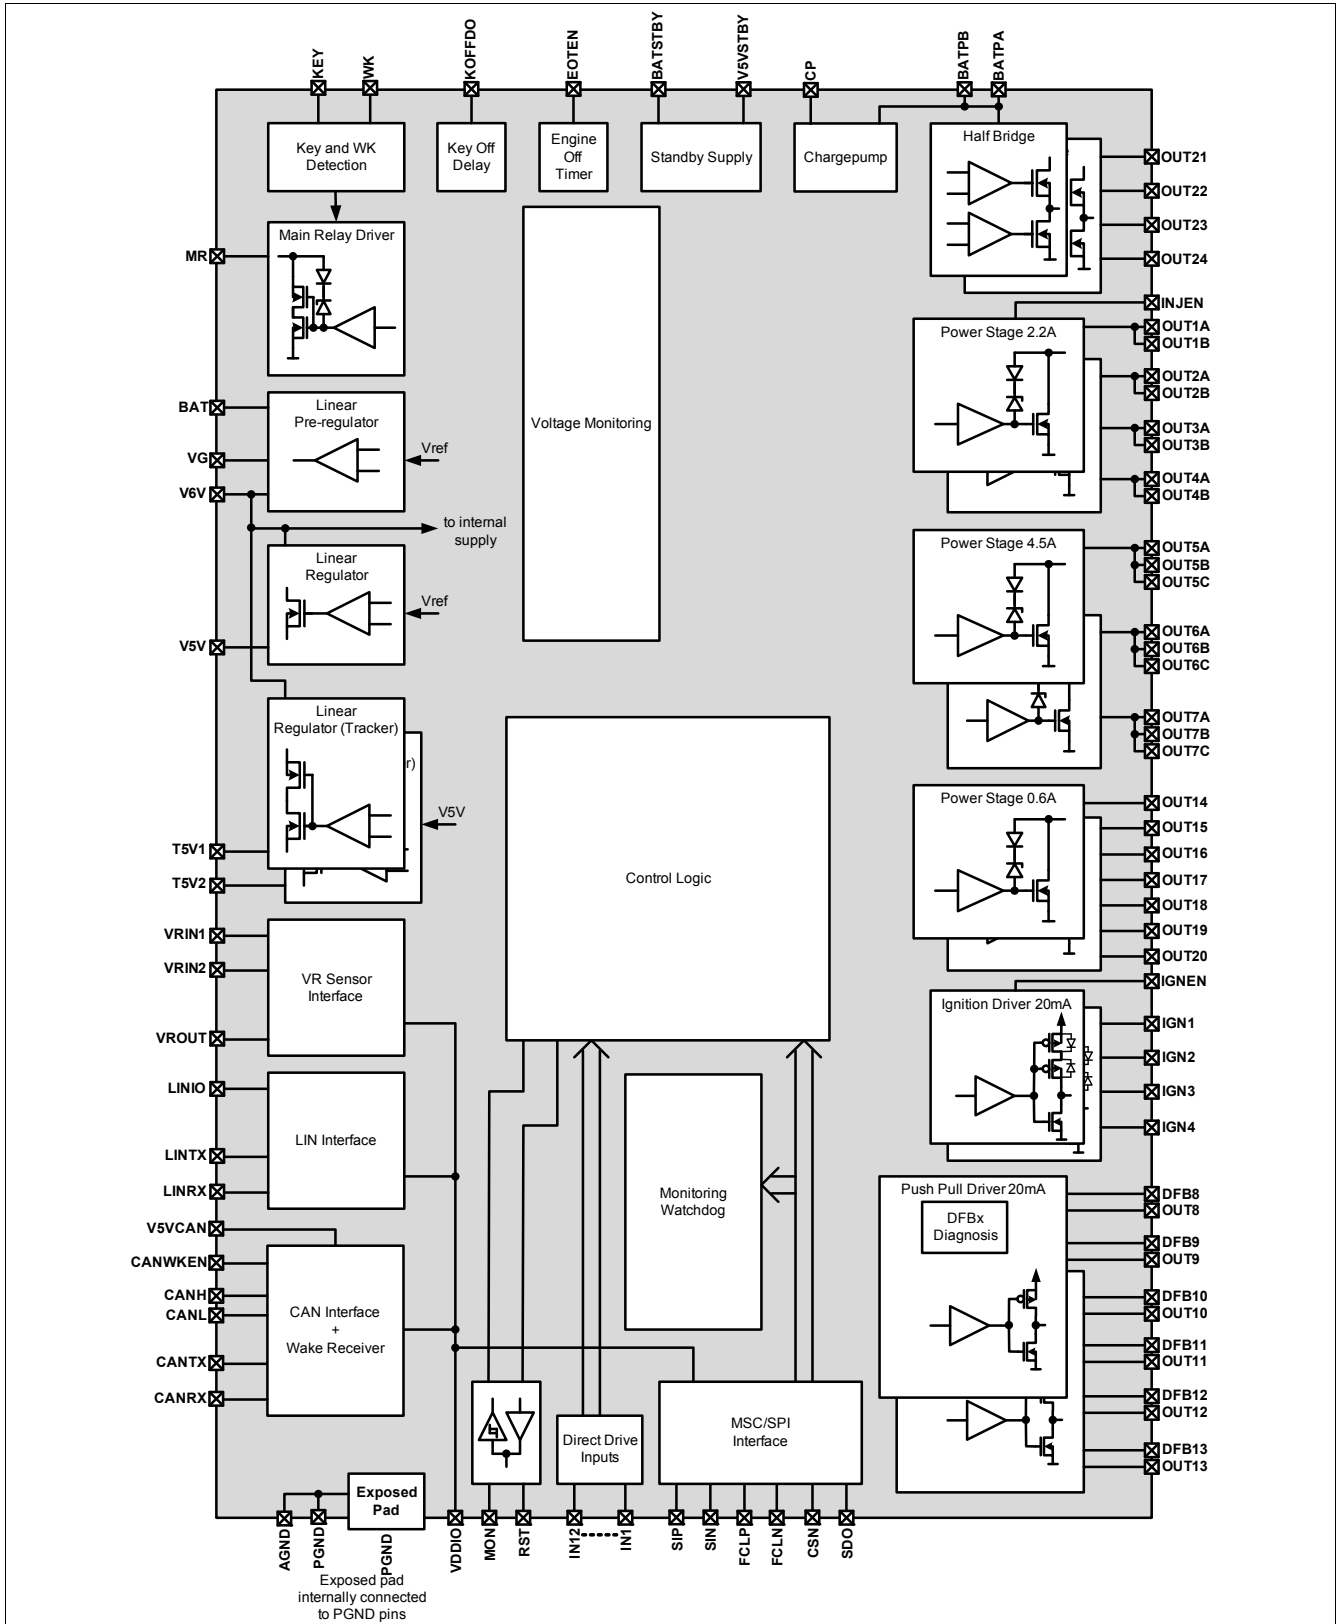

Figure 1 Block Diagram

### 3 Pin Configuration

#### 3.1 Pin Assignment

Figure 2 Pin Configuration

#### 3.2 Pin Definitions and Functions

Pin	Symbol	Function	Function
1	<i>RST</i>	IN/OUT	<b>Reset</b> ; Bidirectional pin for reset functions
2	<i>MON</i>	IN/OUT	<b>Monitor</b> ; Bidirectional pin for monitoring functions
3	<i>CSN</i>	IN	<b>MSC/SPI slave chip select</b> ; Single ended chip select for MSC and SPI
4	<i>SDO</i>	OUT	<b>MSC/SPI serial data output</b> ; Output for MSC and SPI
5	<i>SIP</i>	IN	<b>MSC/SPI Data input</b> ; positive data input of LVDS in MSC mode or single ended data input in SPI mode

Pin Configuration

Pin	Symbol	Function	Function
6	<i>SIN</i>	IN	<b>MSC data input or select input;</b> negative data input of LVDS in MSC mode or select input for SPI mode
7	<i>FCLP</i>	IN	<b>MSC/SPI Clock input;</b> positive clock input of LVDS in MSC mode or single ended clock input in SPI mode
8	<i>FCLN</i>	IN	<b>Select input or MSC clock input;</b> negative clock input of LVDS in MSC mode or select input for single ended mode (SPI or MSC)
9	<i>T5V1</i>	OUT	<b>5V tracker;</b> Supply voltage for off- board sensors
10	<i>T5V2</i>	OUT	<b>5V tracker;</b> Supply voltage for off- board sensors
11	<i>V5V</i>	OUT	<b>5V supply;</b> Supply voltage for main functions of the ECU
12	<i>V6V</i>	IN	<b>Source of external pre-regulator</b>
13	<i>VG</i>	OUT	<b>Gate of external pre-regulator</b>
14	<i>OUT7A</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT7B</i> and <i>OUT7C</i> without any parasitic
15	<i>OUT7B</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT7A</i> and <i>OUT7C</i> without any parasitic
16	<i>OUT7C</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT7A</i> and <i>OUT7B</i> without any parasitic
17	<i>OUT20</i>	OUT	<b>Low side small signal stage;</b>
18	<i>OUT19</i>	OUT	<b>Low side small signal stage;</b>
19	n.c.		leave open or connect to GND
20	<i>VDDIO</i>	Supply	<b>Supply input for logic level inputs and outputs</b>
21	<i>VR0UT</i>	OUT	<b>Output of variable reluctance sensor interface;</b> Digital output to micro controller
22	<i>LINTX</i>	IN	<b>Transmit digital input for LIN interface;</b>
23	<i>LINRX</i>	OUT	<b>Receive digital output for LIN interface;</b>
24	<i>INJEN</i>	IN	<b>Injector enable input;</b>
25	<i>PGND</i>	GND	<b>Power ground;</b> internally connected to cooling tab
26	<i>KOFFDO</i>	OUT	<b>Key off delay output;</b>
27	<i>IGNEN</i>	IN	<b>Ignition enable input;</b>
28	<i>IN1</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stage OUT1,
29	<i>IN2</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stage OUT2
30	<i>IN3</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stage OUT3
31	<i>IN4</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stage OUT4
32	<i>IN5</i>	IN	<b>Parallel input;</b> Input pin for direct control of push pull state IGN1
33	<i>IN6</i>	IN	<b>Parallel input;</b> Input pin for direct control of push pull state IGN2
34	<i>IN7</i>	IN	<b>Parallel input;</b> Input pin for direct control of push pull state IGN3
35	<i>IN8</i>	IN	<b>Parallel input;</b> Input pin for direct control of push pull state IGN4
36	<i>IN9</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stages, could be multiplexed to various stages
37	<i>IN10</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stages, could be multiplexed to various stages
38	<i>IN11</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stages, could be multiplexed to various stages

Pin Configuration

Pin	Symbol	Function	Function
39	<i>INI2</i>	IN	<b>Parallel input;</b> Input pin for direct control of power stages, could be multiplexed to various stages
40	<i>EOTEN</i>	IN	<b>Engine off timer enable input;</b>
41	<i>V5VSTBY</i>	OUT	<b>5V standby supply;</b> Supply voltage in sleep mode
42	<i>CANWKEN</i>	IN	<b>Enable input for remote CAN wake up;</b>
43	<i>CANRX</i>	OUT	<b>Receive digital output for CAN;</b>
44	<i>CANTX</i>	IN	<b>Transmit digital input for CAN;</b>
45	<i>V5VCAN</i>	Supply	<b>5V supply input for CAN;</b>
46	<i>CANH</i>	IN/OUT	<b>CAN bus high;</b>
47	<i>CANL</i>	IN/OUT	<b>CAN bus low;</b>
48	<i>WK</i>	IN	<b>Wake up input;</b> Input signal and supply for MR
49	<i>KEY</i>	IN	<b>Key input;</b> Input signal and supply for MR
50	<i>PGND</i>	GND	<b>Power ground;</b> internally connected to cooling tab
51	<i>VRIN2</i>	IN	<b>Differential input of variable reluctance sensor;</b> Analog input from sensor
52	<i>VRIN1</i>	IN	<b>Differential input of variable reluctance sensor;</b> Analog input from sensor
53	<i>BATSTBY</i>	Supply	<b>Battery input for standby supply;</b> Battery supply voltage standby supply regulator
54	<i>BAT</i>	Supply	<b>Battery;</b> Supply voltage for main functions of the device.
55	<i>MR</i>	OUT	<b>Low side power stage for main relay;</b>
56	<i>OUT18</i>	OUT	<b>Low side power stage;</b>
57	<i>OUT17</i>	OUT	<b>Low side power stage;</b>
58	<i>OUT16</i>	OUT	<b>Low side power stage;</b>
59	<i>OUT1A</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT1B</i> without any parasitic
60	<i>OUT1B</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT1A</i> without any parasitic
61	<i>OUT2A</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT2B</i> without any parasitic
62	<i>OUT2B</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT2A</i> without any parasitic
63	<i>OUT3A</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT3B</i> without any parasitic
64	<i>OUT3B</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT3A</i> without any parasitic
65	<i>OUT4A</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT4B</i> without any parasitic
66	<i>OUT4B</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT4A</i> without any parasitic
67	<i>OUT15</i>	OUT	<b>Low side power stage;</b>
68	<i>OUT14</i>	OUT	<b>Low side power stage;</b>
69	<i>DFB8</i>	IN	<b>Drain Feedback;</b> Related to OUT8
70	<i>OUT8</i>	OUT	<b>Push pull stage;</b> To control on- board MOSFET
71	<i>DFB9</i>	IN	<b>Drain Feedback;</b> Related to OUT9
72	<i>OUT9</i>	OUT	<b>Push pull stage;</b> To control on- board MOSFET
73	<i>DFB10</i>	IN	<b>Drain Feedback;</b> Related to OUT10
74	<i>OUT10</i>	OUT	<b>Push pull stage;</b> To control on- board MOSFET
75	<i>PGND</i>	GND	<b>Power ground;</b> internally connected to cooling tab
76	<i>DFB11</i>	IN	<b>Drain Feedback;</b> Related to OUT11
77	<i>OUT11</i>	OUT	<b>Push pull stage;</b> To control on- board MOSFET

Pin Configuration

Pin	Symbol	Function	Function
78	<i>DFB12</i>	IN	<b>Drain Feedback;</b> Related to <i>OUT12</i>
79	<i>OUT12</i>	OUT	<b>Push pull stage;</b> To control on- board MOSFET
80	<i>DFB13</i>	IN	<b>Drain Feedback;</b> Related to <i>OUT13</i>
81	<i>OUT13</i>	OUT	<b>Push pull stage;</b> To control on- board MOSFET
82	<i>LINIO</i>	IN/OUT	<b>BUS for LIN interface;</b>
83	<i>OUT5A</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT5B</i> and <i>OUT5C</i> without any parasitic
84	<i>OUT5B</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT5A</i> and <i>OUT5C</i> without any parasitic
85	<i>OUT5C</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT5A</i> and <i>OUT5B</i> without any parasitic
86	<i>OUT24</i>	OUT	<b>Half bridge stage;</b>
87	<i>BATPA</i>	Supply	<b>Battery;</b> Supply voltage for half bridges and the charge pump; must be connected to <i>BATPB</i> without any parasitic
88	<i>OUT23</i>	OUT	<b>Half bridge stage;</b>
89	<i>OUT22</i>	OUT	<b>Half bridge stage;</b>
90	<i>BATPB</i>	Supply	<b>Battery;</b> Supply voltage for half bridges and the charge pump; must be connected to <i>BATPA</i> without any parasitic
91	<i>OUT21</i>	OUT	<b>Half bridge stage;</b>
92	<i>OUT6A</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT6B</i> and <i>OUT6C</i> without any parasitic
93	<i>OUT6B</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT6A</i> and <i>OUT6C</i> without any parasitic
94	<i>OUT6C</i>	OUT	<b>Low side power stage;</b> Must be connected to <i>OUT6A</i> and <i>OUT6B</i> without any parasitic
95	<i>CP</i>	OUT	<b>Charge pump;</b> add external capacitance to stabilise charge pump voltage
96	<i>IGN1</i>	OUT	<b>Push pull stage;</b> To control on- or off- board IGBT
97	<i>IGN2</i>	OUT	<b>Push pull stage;</b> To control on- or off- board IGBT
98	<i>IGN3</i>	OUT	<b>Push pull stage;</b> To control on- or off- board IGBT
99	<i>IGN4</i>	OUT	<b>Push pull stage;</b> To control on- or off- board IGBT
100	<i>AGND</i>	GND	<b>Signal ground;</b> internally connected to <i>PGND</i> and cooling tab
Cooling tab <sup>1)</sup>	<i>PGND</i>	GND	<b>Power ground;</b> internally connected PGND pins

1) Cooling tab is also called exposed pad

## 4 General Product Characteristics

General definition:

$V_S$  is the short cut for all battery supplies of the TLE8888-1QK (*BAT, BATPA, BATPB, BATSTBY*) unless otherwise specified

*GND* is the short cut for all grounds of the TLE8888-1QK (*AGND, PGND*) unless otherwise specified.

**Table 2 Absolute Maximum Ratings<sup>1)</sup>**

$T_j = -40$  to  $150^\circ\text{C}$ , all voltages with respect to *GND*, positive current flowing into pin, (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
<b>Voltages</b>							
BATPA, BATPB, OUT8...13, DFB8...13	$V_{BATPA,MR}$ , $V_{BATPB,MR}$ , $V_{OUT8...13,MR}$ , $V_{DFB8...13,MR}$	-0.3	–	40	V	–	P_4.1
CP	$V_{CP,MR}$	-0.3	–	45	V	$-0.3V < V_{CP} - V_{BATPA} < 5V$	P_4.2
OUT1...7, OUT14...20	$V_{OUT1..7,MR}$ , $V_{OUT14..20,MR}$	-0.3	–	50	V	OUTn is switched off, clamping is allowed according <a href="#">Chapter 9.6</a>	P_4.3
V6V	$V_{V6V,MR}$	-0.3	–	10	V	–	P_4.4
VG	$V_{VG,MR}$	-0.3	–	12	V	$V_{VG} - V_{V6V} < 5V$	P_4.5
V5V, V5VSTBY, VDDIO, V5VCAN	$V_{V5V,MR}$ , $V_{V5VSTBY,MR}$ , $V_{VDIO,MR}$ , $V_{V5VCAN,MR}$	-0.3	–	5.5	V	–	P_4.6

- 1) not subject to production test
- 2) Current has to be limited when maximum voltages are exceeded
- 3) according to qualification
- 4) ESD susceptibility, HBM according to EIA/JESD 22-A114F (1.5kΩ, 100pF)
- 5) ESD susceptibility, Charged Device Model “CDM” EIA/JESD22-C101 or ESDA STM5.3.1

**Notes**

1. Stresses above the ones listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as “outside” normal operating range. Protection functions are not designed for continuous repetitive operation.

## 5 Operation Behavior

The TLE8888-1QK has implemented the whole supply of an ECU. Therefore a complex control logic is implemented to provide several operation states.

In this chapter

- the ramp up and down behavior and
- the status of the TLE8888-1QK during special conditions like 5V undervoltage

is described. For the description of the monitoring watchdog module see [Chapter 6](#).

In [Figure 3](#) the block diagram with all blocks affecting the status of the device and the ECU are shown. Following blocks are influenced during the different operation states and reset functions:

- **Serial Interface MSC/SPI:** with the serial interface the setup of the device is done
- **Key input detection:** start signal from key switch (KL15)
- **Wake up input detection:** additional start signal e.g. from external CAN with wake up by bus function
- **Engine off timer:** wake up signal in comparator mode
- **Power supply:** ECU 5V supply and 5V sensor supplies, 5V standby supply
- **Voltage monitoring:** supervision of all supplies (BAT, V5V, T5V1, T5V2)
- **Main relay driver:** controls external main relay to switch battery voltage to an ECU supply pin (see also application setups in [Chapter 17](#))
- **Power stages and half-bridges control block**
- **LIN/K-Line:** transmission mode depends on operation state of the ECU
- **CAN:** transmission mode depends on operation state of the ECU, remote wake up function
- **Reset outputs MON and RST**
- **Monitoring watchdog module:** signature watchdog for safety applications
- **Operation Mode Control**

The operation mode control block consists of:

- ramp up and down sequence control logic
- the reset control logic and
- status output logic.

Figure 3 Block diagram operation mode control

### 5.1 Operation States

In **Figure 4** the state diagram of the whole ramp up and down sequence is shown. There are seven operation states:

- **ECU sleep state:** *KEY* and *WK* input are “low”, no wake up signals from engine off timer or CAN are active, main relay is off, the whole ECU inclusive TLE8888-1QK is not supplied, 5V standby supply is working if pin *BATSTBY* is supplied, engine off timer and CAN wake up circuits are active if enabled and supplied.

- **Supply ramp up state:** *KEY* input or *wake*<sup>1)</sup> are “high” and the supply of the TLE8888-1QK starts working, the voltage of V6V, V5V, T5V1 and T5V2 are ramping up but the voltage levels are below the under voltage threshold. For wake up by *wake*<sup>1)</sup> the ramp up of the main supply has to be finished before the ramp up timer overflow. The main relay is switched on depending on the voltage level at the pin *BAT* (see [Chapter 7.2](#))
- **Normal operation state:** *KEY* input or *wake* are “high” and main relay is switched on depending on the voltage level at the pin *BAT* or the status of bit **MR** in the status register **OpStat0** (see [Chapter 7.2](#)), the whole ECU is supplied and the status of the different functions and registers is according [Table 6](#) and [Table 7](#).
- **Afterrun state:** *KEY* is “low” but afterrun enable bit is set and therefore the whole ECU is supplied, the status of the different functions and registers is according [Table 6](#) and [Table 7](#) and the micro controller can execute afterrun routines
- **Afterrun reset state:** the reset procedure before direct reentry in normal operation is executed if bit **AR** =1 in the configuration register **OpConfig0**
- **General power down state:** the supplies of the ECU (*V5V*, *T5V1*, *T5V2*) are disabled and the power down timer is counting, main relay remains in the switching status and the TLE8888-1QK is supplied to ensure the power down (V5V drops down to 0V) of the ECU, *V5VSTBY* is working if *BATSTBY* is supplied, all functions to external are disabled.
- **Wake clear state:** this state avoids permanent wake up in failure cases. The wake clear command is executed (function according setting bit **WKCLR** in the command register **Cmd0**). All wake signals which are active after the supply ramp up and the general power down state are reset.

1) description see [Figure 4](#), [Chapter 7.2](#), [Chapter 7.4](#) and [Chapter 12.2.4](#)

Figure 4 Operation state diagram

Description of the transitions:

**Table 5 Operation State Transitions**

Transition	Condition	Description
from all states to ECU sleep state	internal supply voltage < internal por threshold and $KEY=0$ and $wake^1)=0^2)$	internal power on reset is active and reset the whole digital logic, ECU sleep state is entered due to no wake up signal at $KEY$ or $wake$
from all states to supply ramp up state	internal supply voltage < internal por threshold and $KEY=1$ or $wake=1^2)$	internal power on reset is active and reset the whole digital logic, supply ramp up state is entered due to a wake up signal at $KEY$ or $wake$
ECU sleep state to supply ramp up state	$KEY > V_{KEY,th}$ or $wake=1$	With a "high" voltage at $KEY$ or $wake$ the wake up of the TLE8888-1QK starts
Supply ramp up state to ECU sleep state	$KEY < V_{KEY,th}$ and $wake=0^2)$	The external supply ramp up is not finished but the wake up signals are low
Supply ramp up state to wake clear state	$KEY < V_{KEY,th}$ and $wake=1^2)$ and $RT\_OF=1$	The $KEY$ signal is low and the wake up signals are active. The ramp up timer has an overflow which indicates a ramp up problem of the external supply (e.g. short to GND). To avoid permanent high current consumption the internal wake signals must be reset to enter the ECU sleep state.
Supply ramp up state to normal operation state	$(KEY > V_{KEY,th}$ or $wake=1)$ and $V5V > V_{uv,V5V}^2)$	normal operation state is entered if the main supply voltage $V5V$ is above the under voltage threshold, $KEY$ is high or one of the wake up conditions are active
Normal operation state to afterrun state	$KEY < V_{KEY,th}$ and $AE=1^2)$	$KEY$ is "low" and afterrun function is enabled: no changes in the setup of the TLE8888-1QK
Normal operation state to ECU sleep state	$AE=0$ and $KEY < V_{KEY,th}$ and $wake=0^2)$	normal shut off
Normal operation state to general power down state	$(PD\_OF=1$ or $SSOT\_OF=1)$ and $KEY < V_{KEY,th}^2)$	$KEY$ is low and watchdog error shut off with overflow of the power down counter or secure shut off due to expired secure shut off timer
Afterrun state to ECU sleep state	$AE=0$ and $KEY < V_{KEY,th}$ and $wake=0^2)$	normal shut off in afterrun mode with the reset of the afterrun enable bit $AE$ by the micro controller
Afterrun state to general power down state	$PD\_OF=1$ or $SSOT\_OF=1$	watchdog error shut off with overflow of the power down counter or secure shut off due to expired secure shut off timer
Afterrun state to normal operation state	$KEY > V_{KEY,th}$ and $AR=0^2)$	reentry of normal operation with $KEY$ on during afterrun operation, no reset is performed ( $AR=0$ )
Afterrun state to afterrun reset state	$KEY > V_{KEY,th}$ and $AR=1^2)$	reentry of normal operation with $KEY$ on during afterrun operation with reset ( $AR=1$ )
Afterrun reset state to normal operation state		transition to normal operation with the next active internal clock edge after entry to the afterrun reset state
General power down state to wake clear state	$PDT\_OF=1$	with the power down timer overflow the reset of the internal wake signals must be performed

**Table 5** Operation State Transitions (cont'd)

Transition	Condition	Description
Wake clear state to ECU sleep state	$KEY < V_{KEY,th}$	after reset of the internal wake signals and <i>KEY</i> is low the ECU sleep state is entered, no unwanted wake up due to a failure condition will occur
Wake clear state to supply ramp up state	$KEY > V_{KEY,th}$	after reset of the internal wake signals and <i>KEY</i> is high the supply ramp up state is entered, no unwanted wake up due to a failure condition at the CAN bus and pin <i>WK</i> will occur

1) *wake* = WKINT or CANWK or EOTWK (see [Chapter 7.2](#), [Chapter 7.4](#) and [Chapter 12.2.4](#))

2) including defined filter times

The two states:

- normal operation
- afterrun

are reflected in the bit **OM** of the status register **OpStat0**.

The power down time is defined with the bits **PDT** of the configuration register **OpConfig0**.

In [Figure 5](#) a sequence with wake up by *KEY* and go to sleep with afterrun mode is shown.

**Figure 5** Ramp up and down sequence diagram with wake up by *KEY* and afterrun mode

## 5.2 Reset and Operation Modes

The TLE8888-1QK provides several supervision functions which lead to some dedicated reset states and special operation modes of the device and the ECU.

There are two bidirectional reset pins MON and RST implemented. For the behavior during reset of the reset pins MON and RST and the other status of the TLE8888-1QK see [Table 6](#) and [Table 7](#).

Following reset functions and special states are implemented:

- **Internal power on reset:** the internal power on reset detection circuit monitors the voltage level of the internal supply. For an internal supply voltage below the internal power on reset threshold the whole digital logic of the TLE8888-1QK is reset which results in the ECU sleep state or supply ramp up state depending on the state of *KEY* and *wake*. If the voltage level for operation is high enough the 6V pre regulator is working. The 5V supplies are disabled till the internal supply level is over the power on threshold level.
- **ECU power on reset:** this is the reset at ramp up of the power supplies and the beginning of the operation. The pins *RST* and *MON* are pulled to GND to reset the micro controller and all devices connected to the pin *MON*. The device is reset to the initial reset status. The reset is released with a voltage at pin *V5V* higher than the **V5V Under Voltage Detection Hysteresis** after  $t_{pu,r}$ .
- **Reset during under voltage of the 5V supply V5V:** this reset occurs during under voltage of the 5V ECU supply. The pins *RST* and *MON* are pulled to GND to reset the micro controller and all devices connected to the pin *MON*. The delayed switch off function is active regarding the configuration setup. The status of the main relay is according to the status of the wake up pins *KEY* and *WK* and the voltage level of the supply pin *BAT*.
- **State during under voltage of the 5V supplies T5V1 and T5V2:** with the under voltage detection of the tracker supplies diagnosis bits are set but there is no effect to the behavior of the device.
- **Reset during over voltage of the 5V supply V5V:** with the over voltage detection of the 5V ECU supply all functions of the device which have an effect externally or can lead to over current or over temperature are disabled (e.g. power stages, LIN/CAN/MSB/SPI communication). The pins *RST* and *MON* are low.
- **State during over voltage of the 5V supplies T5V1 and T5V2:** with the detection of over voltage of the tracker supplies diagnosis bits are set but there is no effect to the behavior of the device.
- **Power stages switch off during over voltage of the battery supply BAT:** For voltages at the supply pin *BAT* higher than the over voltage threshold the power stages are disabled to avoid too high clamping energy during switch off. Damage of the switches is prevented.
- **Watchdog reset:** If the reset counter is incremented and the reset is enabled (bit **WDREN** = 1) the micro controller is reset with a "low" at the pin *RST*. The power stages are disabled and the LIN/CAN communication is set to receive only mode.
- **Software reset from micro controller:** with the software reset command (command register **CmdSR**) the software reset is activated. The device is reset to the reset status defined in **Table 6** and **Table 7**. The activation of the software reset triggers an increase of the power down counter by 1.
- **Reset with an external forced "low" at RST:** With a detected "low" at the *RST* pin the TLE8888-1QK is reset to the reset status defined in **Table 6** and **Table 7**.
- **Power stages switch off with an external forced "low" at MON:** With a detected "low" at the *MON* pin the power stages are disabled (**O1E** to **O24E**, **IGN1E** to **IGN4E** are set to "0"). After *MON*=0 event the power stages must be enabled again.
- **State with time out of the MSC communication:** With the time out of the MSC communication the power stages are disabled (**O1E** to **O24E**, **IGN1E** to **IGN4E** are set to "0"). After the next valid received data frame the power stages must be enabled again.
- **Afterrun reset:** This reset is executed if the bit **AR** of register **OpConfig0** is 1 and the transition from afterrun state to normal operation is triggered (definition see **Table 7**).

1) according the definition in [Chapter 7](#)

2) after release of RST (transition from low to high) there is a time delay of  $t_{del,r}$  before configuration is enabled

3) status for time  $t_{op,r}$

4) pull up of open drain output is active

5) start of watchdog sequence after release of reset

6) SSOT reset due to  $KEY=1$

7) valid for all register bits which are not described in [Table 6](#) or [Table 7](#)

8) During active delayed switch off mode some register bits related to the power stages are not reset, see [Chapter 9.4](#)

**Table 8 Reset Time Definition**

Reset Function		Reset Time at RST Output	Related Status Bits in Register <b>OpStat1</b>
internal power on reset			all registers are reset
ECU power on reset		$t_{pu,r}$	
Under voltage V5V		$t_{pu,r}$	<b>V5VUVR</b>
Over voltage V5V		$t_{pu,r}$	<b>V5VOVR</b>
Watchdog reset		$t_{op,r}$	<b>WDRES</b>
RST reset forced from outside		forced from outside	<b>RSTR</b>
Software reset from micro controller		no effect	all registers are reset <sup>1)</sup>
Afterrun reset	<b>AR="0"</b>	no effect	
	<b>AR="1"</b>	$t_{op,r}$	<b>ARES</b>

1) internal reset with  $t_{int,r}$  active

After a reset with pin *RST* the configuration of the CAN and LIN bus is delayed by the time  $t_{del,r}$  to avoid that undefined micro controller pins are affecting the buses. During this delay time the configuration bits can be changed by a write access to the register.

### 5.3 Electrical Characteristics Operation Behavior

**Table 9 Electrical Characteristics: Operation Behavior**

$V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_j=-40$  to  $150^\circ C$ , all voltages with respect to ground, positive current flowing into pin (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
Internal power on reset threshold	$V_{por,int,th}$	–	–	2.8	V	of internal supply voltage	P_5.3.1
Supply voltage range for internal supply	$V_{BATP,int}$	4.5	–	–	V	only valid if the charge pump has ramped up before voltage drop, both condition must be fulfilled to ensure no internal power on reset	P_5.3.2
	$V_{V6V,int}$	3.5	–	–	V		

#### Power Down Timer

Power down time 1	$t_{pd,1}$	–	100	–	ms	–	P_5.3.3
Power down time 2	$t_{pd,2}$	–	200	–	ms	–	P_5.3.4
Power down time 3	$t_{pd,3}$	–	300	–	ms	–	P_5.3.5
Power down time 4	$t_{pd,4}$	–	400	–	ms	–	P_5.3.6
Power down time accuracy	$t_{pd,a}$	-10	–	+10	%	–	P_5.3.7

#### Ramp Up timer

Ramp up time	$t_{ru}$	185	–	650	ms	–	P_5.3.8
--------------	----------	-----	---	-----	----	---	---------

## 6 Monitoring Watchdog Module (Signature Watchdog)

The watchdog function is intended for a temporal and logical monitoring of the micro controller's program sequence. In **Figure 6** the block diagram of the monitoring module is drawn. The module has an interface to the MSC/SPI block. The monitoring of the micro controller is done by the separate check of the timing with the window watchdog and the logical operation check by the functional watchdog. Therefore the micro controller must send a window watchdog service command for the window watchdog and four response bytes for the functional check. The results of the checks affect the corresponding counter (window watchdog error counter or functional watchdog pass counter). Additionally a total error counter module is implemented which detects the occurrence of watchdog errors (the timing check or the functional is not passed) and changes the status of the total error counter accordingly.

For the independent functional watchdog and the total error counter a heartbeat is implemented to define the increment timing of both functions.

**Figure 6** Block diagram of the Monitoring Watchdog Function

**Monitoring Watchdog Module (Signature Watchdog)**

The status of the counters (window watchdog error counter, functional watchdog pass counter and total error counter) and the corresponding overflow signals are inputs to the watchdog reset, power down counter and the secure shut off timer. This information is used to affect the operation status of the TLE8888-1QK and the status of the pins *MON* and *RST*.

The software of the micro controller has to make sure that the program sequence and any safety critical parts of the micro controller are self tested by performing related routines according to the received questions.

## 6.1 Window Watchdog

For the timing check the micro controller has to send periodically the window watchdog service command **WWDServiceCmd**. The window watchdog is triggered correctly if the command is received inside the open window of the window watchdog sequence. The check result is used to change the value of the window watchdog error counter. If the check is passed the counter will be decremented and for errors it will be incremented. Additionally a write access to configuration register **WWDConfig0** causes also an incrementation of the window watchdog error counter. The incrementation of the window watchdog error counter (error is occurred) is an input for the total error counter ([Chapter 6.3](#)). In [Figure 7](#) the state machine of the window watchdog is shown.

The values for incrementation or decrementation can be set in the configuration register **WWDConfig1**. The window watchdog error counter is a 6 bit counter. The influence of the counter values to the operation behavior is shown in [Table 12](#) and [Table 13](#).

The window watchdog sequence for the timing check consists of a closed window followed by an open window (see [Figure 8](#)). A watchdog sequence starts with:

- the release of a reset of the monitoring module (see [Table 6](#) and [Table 7](#) in [Chapter 5.2](#))
- a window watchdog service command
- a write to the window time configuration register **WWDConfig0**
- a timer overflow of the watchdog timer

In [Figure 8](#) the two parts of one watchdog sequence are shown. After the power on reset it is running in an endless loop with the defined time for the open and closed window. It is only stopped at active reset signals or outside

Monitoring Watchdog Module (Signature Watchdog)

normal operating conditions [Table 6](#) and [Table 7](#) in [Chapter 5.2](#).

The timing of the window watchdog sequence can be set with a write command to the configuration register [WWDConfig0](#) or directly with the data bits of the [WWDServiceCmd](#). With a write access to the configuration register [WWDConfig0](#) the watchdog window sequence is started and the window watchdog error counter is incremented.

The check is passed if the command is received inside the open window. A command send too early or a missing command leads to an error. In the diagnosis register [WdDiag](#) the bit [WWDSCCE](#) signalizes a window watchdog service command received too early and the bit [WWDTO](#) signalizes a time out (no window watchdog service command received before end of open window) of the last sequence. The diagnosis information is not cleared with the read out.

The bit [WWDSCR](#) in the status register [WdStat0](#) signalizes a received window watchdog service command at the last watchdog sequence. The reset of this bit is done with a readout of the bit or with the window watchdog time-out.

Figure 7 State Diagram of the Window Watchdog Module

Figure 8 Watchdog Sequence Timing

## 6.2 Functional Watchdog

For the functional check the micro controller has to send with the commands **FWDRespCmd** (functional watchdog response command) or **FWDRespSyncCmd** (functional watchdog response and synchronisation command) the right four response bytes to the actual question defined by the TLE8888-1QK. The response bytes are checked for correctness.

A pass of the check triggers a decrement of the functional watchdog pass counter. A functional watchdog error (FWD error) is not affecting the functional watchdog pass counter but it is used for the total error counter as an input signal (see [Chapter 6.3](#)). A FWD error is defined as:

- received response byte 0 with **FWDRespCmd** and minimum one of the response bytes are wrong
- received response byte 0 with **FWDRespSyncCmd** and minimum one of the response bytes are wrong
- the watchdog heartbeat timer period synchronisation command **WDHBTPSyncCmd** is received

In the diagnosis register **WdDiag** the bit **FWDREA** signalizes an error of the received response bytes to the actual question and the bit **FWDREL** signalizes an error of the response bytes of the last answer. With a read out the diagnosis bits are not cleared.

To detect that the functional check is missing a heartbeat is implemented. With an heartbeat event the functional watchdog pass counter is incremented. An heartbeat event occurs:

- with expiring of the heartbeat period timer or
- with receiving the watchdog heartbeat period synchronisation command **WDHBTPSyncCmd** (response counter is also reset) or
- with receiving the functional watchdog response and synchronisation command **FWDRespSyncCmd** if response byte 0 is received

The heartbeat period can be set by a write access to the configuration register **WDConfig0** or by the watchdog heartbeat period synchronisation command **WDHBTPSyncCmd**. If the data is 000 0000<sub>B</sub> the value of the heartbeat period is not changed.

Behavior of the heartbeat period in case of changing the period time:

---

 Monitoring Watchdog Module (Signature Watchdog)

- **WDHBTPSyncCmd**: the response counter and the heartbeat timer are reset and a heartbeat event is triggered, the new value of the period is executed with next period.
- write access to the configuration register **WDCConfig0**: the new value of the period is effective after the write command. If the new value is lower than the actual heartbeat timer value then the heartbeat event is immediately triggered otherwise the actual period length is immediately changed to the new value.

The functional watchdog pass counter is a six bit counter (see status register **FWDStat0**). The values for incrementation or decrementation can be set in the configuration register **FWDConfig**. The influence of the counter values to the operation behavior is shown in **Table 12** and **Table 13**.

In **Figure 9** the state machine of the functional watchdog is shown. There are two possible principles available to serve the function watchdog:

- unsynchronized heartbeat and use of functional watchdog response command **FWDRespCmd** and write access to the configuration register **WDCConfig0** to change the heartbeat period time or
- heartbeat is started with receiving the functional watchdog response and synchronisation command **FWDRespSyncCmd** and use of the watchdog heartbeat period synchronisation command **WDHBTPSyncCmd** for changing the heartbeat period

The commands can be used in all possible combinations without restrictions. Using **FWDRespCmd** has the advantage that with fast correct responses the decrement of the functional watchdog pass counter can be speed up.

The bit **FWDKQ** in the configuration register **WDCConfig1** is used to enable the keep question function for the functional watchdog. If the bit is set in case of a passed functional check the next functional check procedure is done with the same question if minimum one of the bits **WWDSCE** or **WWDTO** is set (window watchdog error).

Monitoring Watchdog Module (Signature Watchdog)

Figure 9 Functional Watchdog State diagram

### 6.2.1 Question and Response Definition

The bits **FWDQUEST** in the watchdog status register **FWDStat1** represent the actual valid question. The reset value is 0000<sub>B</sub> and it will be changed regarding the definition of the state machine for the monitoring module (see **Figure 7**). The expected response is shown in **Table 11**. The answer of the micro controller is done by a write access to the command registers **FWDRespCmd** or **FWDRespSynchCmd**. The actual value of the bits **FWDRESPC** in the watchdog status register **FWDStat1** defines the interpretation of the 8 bit content of these commands as RESP3 to RESP0 (definition see **FWDRESPC**).

**Monitoring Watchdog Module (Signature Watchdog)**

The definition of the next question is done with a pseudo random algorithm. With the bit **FWDQG** in the configuration register **WDConfig1** the generation algorithm for the questions is defined. There are two settings:

- question pattern length 16: 16 question repeated every 16th watchdog sequence with a minimum hamming distance of 3
- question pattern length 256: every 256 question the order of the 16 questions is repeated, minimum hamming distance is 1

**Table 11 Questions and related Response**

QUEST[3:0]	RESP3	RESP2	RESP1	RESP0
0	FF	0F	F0	00
1	B0	40	BF	4F
2	E9	19	E6	16

D	17	E7	18	E8
E	4E	BE	41	B1
F	01	F1	0E	FE

**6.3 Total Error Counter Module**

The total error module is used to count the errors of the window watchdog and the functional watchdog. In **Figure 10** the error check state machine is shown. If a watchdog error of the functional or the window watchdog occurs the state machine enters the state “error occurred” and with the next heartbeat event (definition see **Chapter 6.2**) the total error counter is incremented.

The counter is also incremented if a functional watchdog error or at the same time a window watchdog error occurs by using the **FWDRespSyncCmd**. With the **WDHBTPSyncCmd** always an increment of the total error counter is done. A decrement of the total error counter is only possible by using the **FWDRespSyncCmd** and no errors are occurred.

The decrement and increment value of the total error counter can be set with the configuration register **TECConfig**. The status of the total error counter is available in the status register **TECStat**.

Figure 10 State diagram of the Error check State machine for the Total Error Counter Module

### 6.4 Watchdog Reset Counter

The watchdog reset counter is a three bit counter (bits **RESC** in **WdStat0**) and is triggered by an overflow of one of the three counters of the monitoring functions (see **Figure 11**). The reset counter can only be incremented by 1. Each time the watchdog reset counter changes the value a watchdog reset occurs depending on the status of watchdog reset enable bit **WDREN** in the configuration register **WDCConfig1**. The counter stops counting if **WDREN** = “0” or at full scale. There are no further resets if full scale is reached. The behavior at the different reset conditions is defined in **Chapter 5.2 Table 6** and **Table 7**.

### 6.5 Power Down Counter

There are three power down counters with three bits implemented. The window watchdog power down counter (bits **WWDPC** in status register **WdStat0**) is triggered by an overflow of the window watchdog error counter, the functional watchdog power down counter (bits **FWDPC** in status register **WdStat1**) is triggered by an overflow of the functional watchdog pass counter and the total error power down counter (bits **TECPDC** in status register **WdStat1**) is triggered by an overflow of the total error counter (see **Figure 11**).

If a trigger occurs the dedicated power down counter is incremented by 1. Additionally all three power down counters are incremented by 1 if a software reset occurs. The power down counters are reset if the ready state is reached (see **Table 12** and **Table 13**).

With an overflow of minimum one of the three power down counters a power down of the TLE8888-1QK is performed if **KEY** is “low” (see **Chapter 5.1**). This function can not be disabled. The behavior at the different reset conditions is defined in **Chapter 5.2 Table 6** and **Table 7**.

### 6.6 Secure Shut Off Timer

The secure shut off timer (SSOT) is reset with **KEY** = 1 and the timer starts with an overflow of one of the three counters of the monitoring functions (see **Figure 11**) if it is enabled with **KEY** = 0. If the timer is expired after the **Secure shut off time** a power down of the TLE8888-1QK is performed (see **Chapter 5.1**).The behavior at the different reset conditions is defined in **Chapter 5.2 Table 6** and **Table 7**.

Monitoring Watchdog Module (Signature Watchdog)

### 6.7 Operation State Definition and Reset Generation

The values of the three counter of the monitoring module are affecting the operation state of the TLE8888-1QK. There are three states defined:

- the safe state: this is the reset state. The bits **O1E** to **O24E** and **IGN1E** to **IGN4E** in the configuration register **OEConfig0** to **OEConfig3** are set to "0" to ensure that all actuators are switched off.
- ready state: the device can be operated without restrictions.
- watchdog reset: a reset is performed according the definition in **Table 6** and **Table 7**.

The definition of the three states is shown in **Table 12**. The states are affecting the status of the pins *MON* and *RST*, the power down counter, the secure shut off timer and the reset counter (definition see **Table 13**).

**Table 12 Definition of Reset, Safe and Ready State**

Safe State	WWDEC > 32 <sub>D</sub> OR FWDPC > 32 <sub>D</sub> OR TEC > 32 <sub>D</sub>
Ready State	WWDEC < 33 <sub>D</sub> AND FWDPC < 33 <sub>D</sub> AND TEC < 33 <sub>D</sub>
Watchdog Reset	WWDEC overflow OR FWDPC overflow OR TEC overflow (for all counters > 63 <sub>D</sub> )

**Table 13 System Reaction to the watchdog status**

	Ready State	Safe State	Watchdog Reset
<i>RST</i>	1	1	0 <sup>1)</sup>
<i>MON</i>	1	0	0
Power stages	no influence of normal operation	disabled	disabled
<b>O1E</b> to <b>O24E</b> , <b>IGN1E</b> to <b>IGN4E</b>	X	0	0
WWD error counter FWD pass counter Total error counter	no effect	no effect	reset <sup>1)</sup>
Reset counter	no effect	no effect	increment by 1
Window watchdog power down counter Total error power down counter Functional watchdog power down	reset	no effect	increment by 1 regarding the overflow source
Secure shut off timer	no effect	no effect	start of timer with the first overflow if <i>KEY</i> = 0

1) occurs for the defined reset time if watchdog reset is enabled

Monitoring Watchdog Module (Signature Watchdog)

Figure 11 Block diagram of the Reset Generation

**Behavior of the WWD error counter, the FWD pass counters and the total error counter in case of over and underflow:**

The counters are designed to keep the same value:

- at incrementation if the new counter value is higher than the full scale value of the counter and
- at decrementation if the new counter value is lower than zero.

In [Figure 12](#) an example is shown.

Figure 12 Example of WWD error counter behavior with decrement and increment value of 14d

### 6.8 Synchronisation of Window Watchdog Sequence and Heartbeat

In Figure 13 the relation between the heartbeat clock generation, the total error counter and the window watchdog sequence generation is shown. The window watchdog sequence generation and the heartbeat period generation have the same clock base with the accuracy of  $t_{w,a}$ .

The value of the pre-divider and the heartbeat timer can be read out with the status registers **WDHBT0** and **WDHBT1**. This can be used to measure the actual internal clock frequency. Therefore the value of the pre-divider and the heartbeat period counter must be sampled by sending a **Cmd0** command with an activated **WDHBTS** bit. With this command the value of the two registers are stored in the related status registers and the readout can be done.

With two sampled values the micro controller can correct the time information by the value of the actual frequency of the TLE8888-1QK. With such a correction of the micro controller timing check it is possible to use smaller open window times to improve the performance of the timing check. Additional it is possible to use this information for synchronization purpose for the check of the monitoring function of the TLE8888-1QK inside the micro controller.

## 7 Wake Up Detection and Main Relay Driver

The TLE8888-1QK integrates a complex wake up functionality with two wake up pins (*KEY* and *WK*), engine off timer, CAN wake up and the main relay driver. There are several possibilities to initiate the start up of the device:

- a positive voltage at the pin *KEY* or at the pin *WK*
- a dominant pulse at the CAN inputs *CANH* and *CANL* for the wake up time (description see [Chapter 12](#))
- after expiration of the defined time of the engine off timer in comparator mode

With minimum one valid wake up signal the pre regulator and the main supply start the ramping up due to voltage at the battery supply pin *BAT* and the drain of the external MOSFET of the pre regulator. The switch on of the main relay depends on the wake up signal and the voltage level at the pin *BAT*. For a wake signal from the pin *KEY* the main relay is always switched on. For the other cases the main relay is only switched on if the voltage of the pin *BAT* is below the detection threshold.

With the bit **WKCLR** in the command register **Cmd0** the internal status of the detection at pin *WK*, engine off timer and CAN wake up are reset (description see [Chapter 7.2](#), [Chapter 7.4](#) and [Chapter 12.2.4](#)). The supply for the engine off timer and the CAN wake receiver is *V5VSTBY*.

Figure 14 Block Diagram of the Key Detection, Wake Up Detection and Main Relay Driver

**Table 15 Switching Behavior of Main Relay at Start Up (Transition ECU Sleep to Supply Ramp Up Mode)**

$KEY = 0, WK = EOTWK = CANWK = 0$	-	<i>MR</i> is switched off	Supply is off
$KEY = 1, WK = EOTWK = CANWK = X$	-	<i>MR</i> is switched on	Supply is switched on
$KEY = 0, WK$ or $EOTWK$ or $CANWK = 1$	$BAT < V_{BAT,th}$	<i>MR</i> is switched on	
$KEY = 0, WK$ or $EOTWK$ or $CANWK = 1$	$BAT > V_{BAT,th}$	<i>MR</i> is switched off	

### 7.1 Wake Up Detection by Pin *KEY* and Key Off Delay

The input pin *KEY* is implemented to detect the status of the key switch in the car. With a high signal the start up of the TLE8888-1QK is initiated. During start up the implemented circuitry provides also the supply for switching the main relay. A deglitch filter is implemented to be robust against disturbances (see [Figure 16](#)). After ramp up the supply of the main relay is provided by the internal supply. To provide a direct access from the *KEY* signal to actuators a key off delay function is implemented.

**Figure 15 Block Diagram of the Key Detection**

In [Figure 16](#) the effect of the filter time is shown. The status of the pin *KEY* including the filter time is reflected in bit *KEY* in the status register [OpStat0](#).

**Figure 16** Function of Key detection filter time

The key off delay function provides the *KEY* signal at the open drain output *KOFFDO*. The positive edge is delayed by the **Key Detection Filter Time** and the negative edge by the **Key Off Delay Time 1** to **Key Off Delay Time 4** (according setup of the bits **KOD** in register **OpConfig0**) if the supply is available.

**Figure 17** Timing Diagram of the Key Off Delay

## 7.2 Wake Up Detection by Pin *WK*

The pin *WK* is used e.g. for an external CAN device with wake up function on the ECU. With a high signal the start up of the TLE8888-1QK is initiated. During ramp up the supply for the main relay circuit is provided by the active wake up pin *WK*. After ramp up the supply of the main relay circuit is provided by the internal supply. In **Figure 18** the block diagram of the wake up detection by pin *WK* is shown.

**Figure 18** Block Diagram of the Wake Up Detection

For wake up by pin *WK* special functions are implemented.

- main relay is switched on depending on the voltage level at pin *BAT* (see [Table 15](#))
- power down procedure in case of a permanent *WK* = "1" and a blocked micro-controller (see description in [Chapter 5.1 Operation States](#))
- wake clear bit *WKCLR* in the command register *Cmd0* to clear the internal wake up signal in case of permanent *WK* = "1" signal
- deglitch filter of  $t_{WK,f}$  for positive and negative edge at pin *WK*

In [Figure 19](#) the effect of the filter time is shown. The status of the pin *WK* including the filter time is reflected in bit *WK* in the status register *OpStat0*.

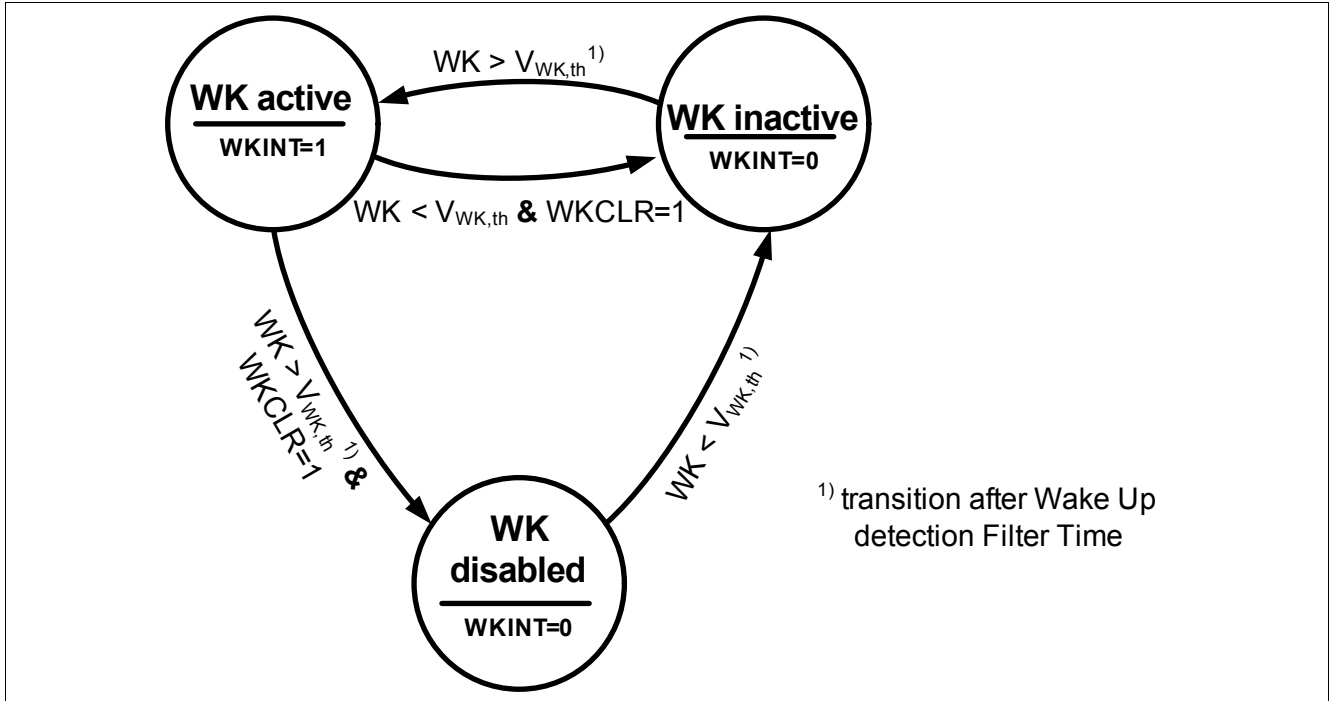

**Figure 19** Function of *WK* detection filter time

To realize the power down procedure an internal wake up signal *WKINT* is used (status see bit *WKINT* in the status register *OpStat0*). In [Figure 20](#) the state diagram of the internal wake signal generation is shown. With a positive edge at pin *WK* the internal signal *WKINT* is set to "1" and a wake up is triggered. With a wake up clear command (set bit *WKCLR* to "1" in command register *Cmd0*) *WKINT* is reset (see [Figure 22](#)). The next wake up by pin *WK*

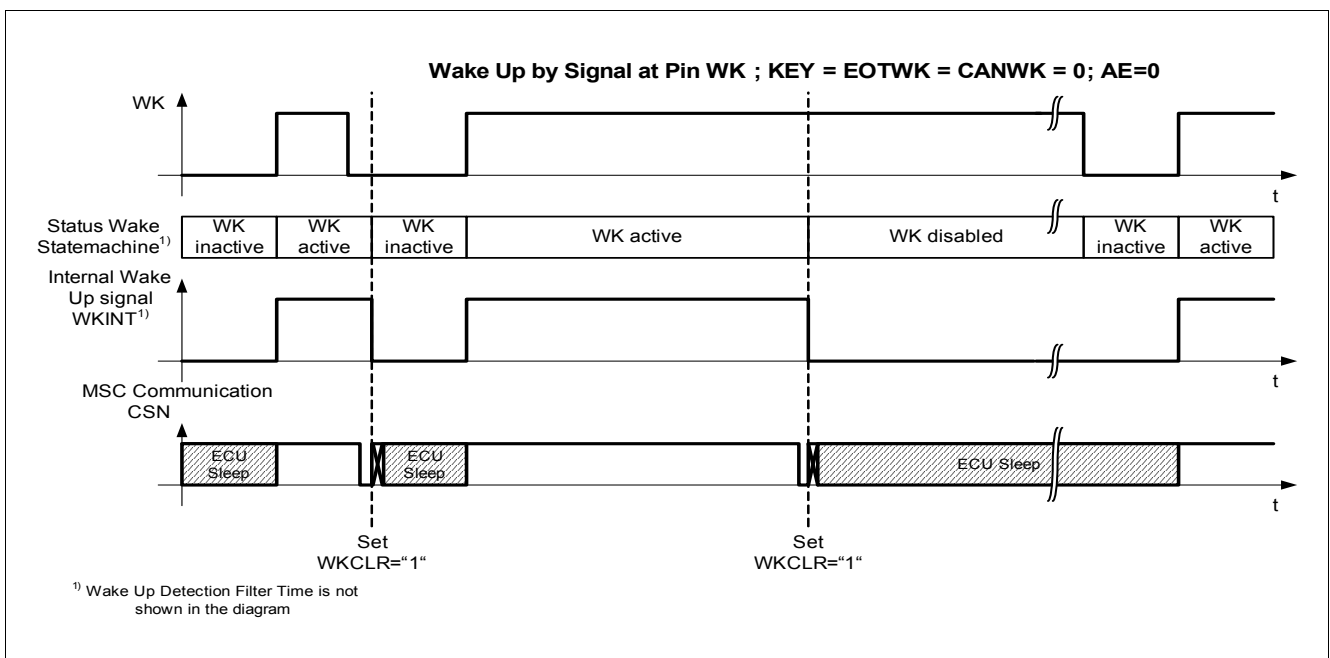

Wake Up Detection and Main Relay Driver

is only detected with a positive edge at pin *WK*. A permanent high level at pin *WK* doesn't lead to permanent wake up situation. Details of the operation behavior see [Chapter 5.1 Operation States](#).

**Figure 20 State Diagram of the Wake State Machine for Internal Wake Signal**

At the beginning of the functional diagram of [Figure 21](#) a normal wake up sequence with a wake signal of the pin *WK* is shown. In the second part of the diagram the signal of pin *WK* stick at high (e.g. short to battery) and the micro controller must send a wake clear command (bit *WKCLR*=1 in command register *Cmd0*) for entering the ECU sleep mode. With a low at pin *WK* the wake state machine is set to the state “WK inactive” and a wake up by pin *WK* is enabled.

**Figure 21 Functional Diagram for Internal Wake Signal**

Figure 22 Functional Diagram of Detection of Two Internal Wake Signals

### 7.3 Main Relay Driver

The main relay driver is designed to switch on the main relay of engine management applications. It integrates a reverse protected low side switch with active clamping freewheeling. The output is protected against overload with an over-temperature detection and an over-current protection circuit. At low battery voltage ( $V5V$  main supply is below under voltage detection threshold e.g. during cranking) the main relay stays on. The on resistance is related to the supply voltage at pin *BAT* and is defined down to 4.5V.

The main relay is automatically switched on with a wake up signal according to [Table 15](#). The main relay is normally switched off automatically according the power down procedure defined in [Chapter 5](#).

With write access to the command bit **MRON** of the command register **Cmd0** the main relay can be switched additionally by MSC/SPI control according to the status of *KEY*, *WK*, *EOTWK* and *CANWK* (see [Table 16](#)). The status of the main relay is available in the status register **OpStat0** bit **MR**.

Table 16 Effect of MSC/SPI Write Command Bit **MRON**

<i>KEY</i> = 0, <i>WK</i> = <i>EOTWK</i> = <i>CANWK</i> = X	<b>MR</b> is switched according to write command
<i>KEY</i> = 1, <i>WK</i> = <i>EOTWK</i> = <i>CANWK</i> = X	<b>MR</b> is always switched on

The main relay driver is protected against over-current and over-temperature. In the case of over-current and/or over-temperature the output is switched off and is switched on again after release of the failure condition. This leads to a repetitive switching. A minimum off time  $t_{MR,off}$  is implemented to ensure no destruction due to repetitive switching.

### 7.4 Engine Off Timer

The engine off timer is integrated to measure the time in ECU sleep mode. Additionally the comparator mode is implemented to wake up the TLE8888-1QK after a defined time. It is internally supplied out of the standby supply pin *V5VSTBY*. With the pin *EOTEN* the function is enabled with a connection to *V5VSTBY* and disabled with a connection to *AGND*. It consists of an oscillator optimized for low current operation, a counter and a comparator. The counter counts up to 36 hours and if the counter value reaches the comparator threshold an internal wake up signal is generated. The activation of the comparator mode is done with a definition of a

Wake Up Detection and Main Relay Driver

comparator threshold greater than 0000<sub>H</sub> in configuration registers **EOTConfig0** and **EOTConfig1**. There are two operation modes implemented:

- **Counter Mode:** only counter is working, no wake up with comparator threshold
- **Comparator Mode:** counter operation like counter mode, additional wake up with comparator threshold

In comparator mode the internal EOTWK flag is set if the counter is equal to compare value in the configuration registers **EOTConfig0** and **EOTConfig1**. The reset of the EOTWK flag is done with the bit **WKCLR** in the command register **Cmd0** if the counter value is not equal to the compare value.

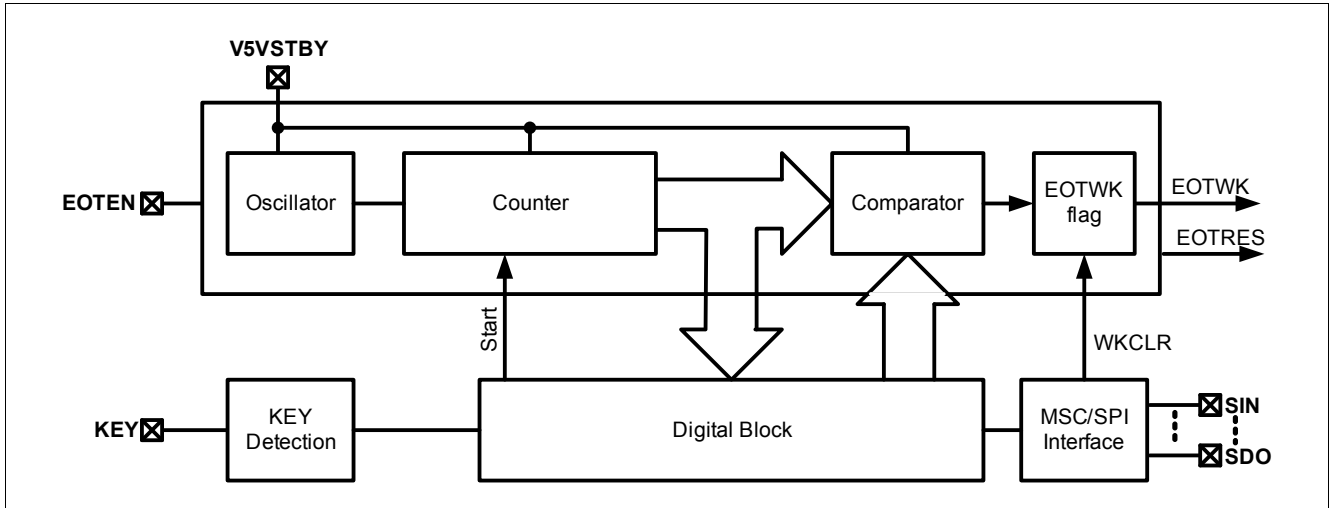

Figure 23 Block Diagram Engine Off Timer

The start of the counter can be configured with the bit **EOTCONF** in the configuration register **OpConfig0** to

- start by **KEY** signal (reset value) and
- start by MSC command

With the falling edge of the **KEY** signal or with the execution of the MSC command the counter is reset and starts counting (see **Figure 24**). The start command is performed with setting the bit **EOTS** to “1” in the command register **Cmd0**.

The status bit **EOTRES** (register **OpStat1**) is implemented to highlight that a standby reset has happened. With the start of the counter this bit is reset. Therefore the status of this bit must be readout before the start of the engine off timer.

The 24 bits of the counter are available in the status register **EOTStat0**, **EOTStat1** and **EOTStat2**. For easier access to the engine off timer status the multiple read command **MSCReadDiag0EOT** is implemented.

After wake up the counter doesn't stop counting. A readout of the counter value doesn't stop counting. With this behavior it is possible to measure the counting time with the micro controller (see **Figure 25**).

With a read out of two counter values in a defined time a correction factor can be calculated (difference of counter values divided by the time between the two read outs). With this measurement of the correction factor only the variation caused by the temperature of the timer are effective. The absolute variations are corrected by the correction factor. There are no restrictions for the measurement time but due to the resolution of the counter a minimum measurement time  $\Delta t$  of 1s is recommended.

After power up of the engine off timer circuit with a supply ramp up at pin **V5VSTBY** the counter value and the comparator threshold are reset to the reset value. Additionally the bit **EOTRES** in the status register **OpStat1** is set to “1”.

Any other resets like ECU power on reset have no impact to the engine off timer counter. The compare configuration register **EOTConfig0** and **EOTConfig1** are cleared with an ECU power on reset.

The counter stops counting at full scale. If a standby supply reset occurs the counter stops counting and is reset to “0”.

Wake Up Detection and Main Relay Driver

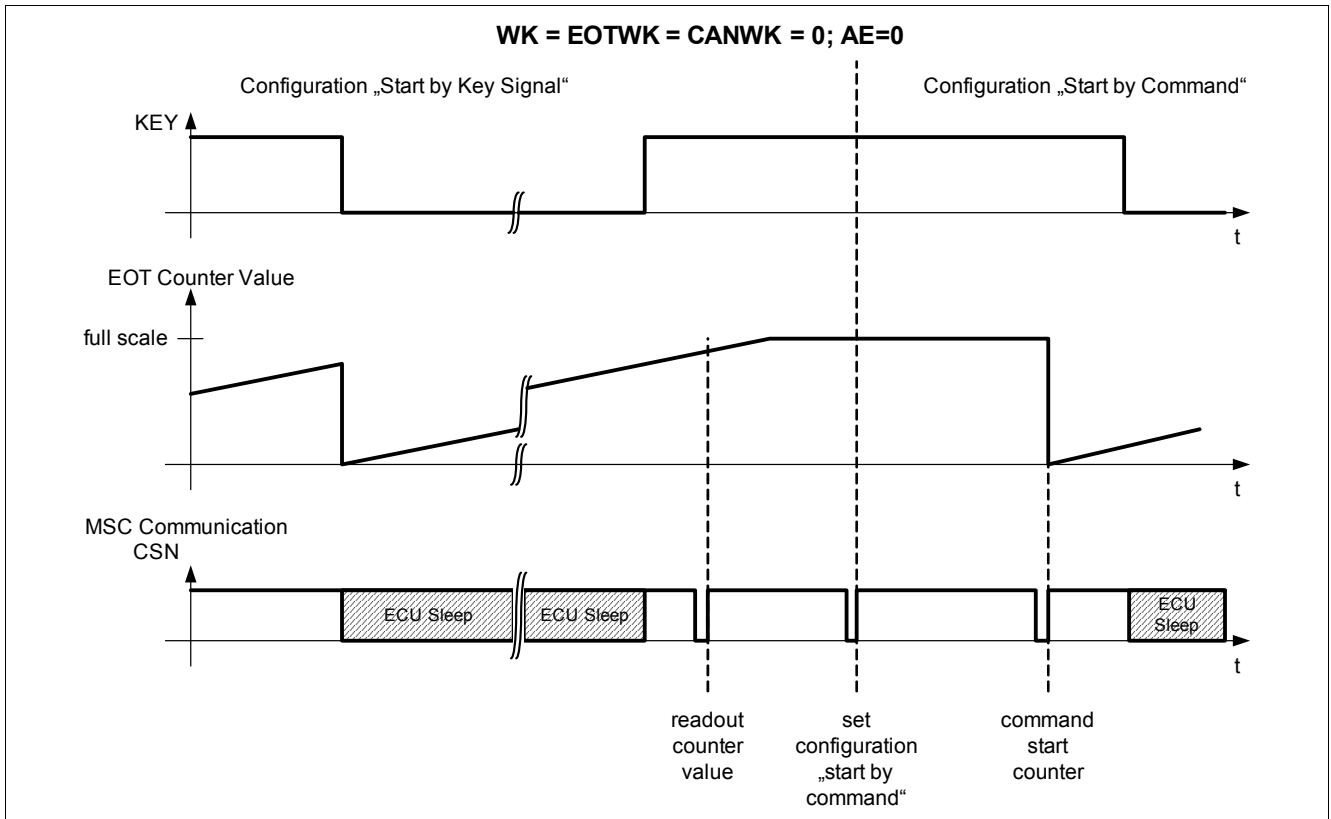

Figure 24 Function Diagram Engine Off Timer Counter Mode

Figure 25 Function Diagram Engine Off Timer Correction Factor Measurement

Wake Up Detection and Main Relay Driver

In comparator mode there is no difference in the behavior of the counter as described above. Additionally a comparator threshold different to 0000<sub>H</sub> for wake up is defined in the configuration register **EOTConfig0** and **EOTConfig1**. The comparator mode is enabled with a threshold value different to 0000<sub>H</sub>. If the counter value is equal to the comparator threshold the internal wake up signal EOTWK (status see bit **EOTWK** in the status register **OpStat0**) of the TLE8888-1QK is active (see **Figure 26**).

With a wake up clear command (set bit **WKCLR** to "1" in command register **Cmd0**) the internal EOTWK signal is reset.

**Table 17 Counter Definition**

EOTC[23:0]		
000000 <sub>H</sub>	reset value	
000001 <sub>H</sub> to FFFFFFF <sub>H</sub>	1/128s to 131071s = 36h + 24min + 31s	time resolution 1/128s

**Table 18 Comparator Threshold Definition**

EOTTH[15:0]		
0000 <sub>H</sub>	reset value	comparator mode disabled
0001 <sub>H</sub> to FFFF <sub>H</sub>	2s to 131070s = 36h + 24min + 30s	comparator mode enabled, time resolution 2s

## 8 Power Supply

The power supply unit generates the internal supply (including supply for CAN and pre-drivers, voltage reference and current biasing), the main supply voltage for the ECU ( $V5V$ ) and sensor supplies for off-board sensors ( $T5V1$  and  $T5V2$ ). All supplies start working by the wake up signal generated by the key and wake up detection (see [Chapter 7.2](#) for details).

A linear pre-regulator with an external logic level power MOSFET is implemented to keep the power dissipation of the TLE8888-1QK low. The precise voltage supplies for the ECU and the sensor supplies are integrated inclusive the power transistor. All supplies with low drop functionality (main supply  $V5V$ , pre-regulator, sensor supplies  $T5V1/T5V2$ ) are using an integrated charge pump to provide low drop behavior at low battery voltages.

Figure 27 Block diagram of the power supply

### 8.1 Pre-Regulator

The pre-regulator uses an external logic level power MOSFET and regulates the voltage at pin  $V6V$ . The voltage at the pin is also the input voltage for the main supply of the ECU ( $V5V$ ), the sensor supplies ( $T5V1$ ,  $T5V2$ ) and the internal supply. The circuit is designed for low drop operation.

It's not allowed to load the external MOSFET with anything else than  $V6V$ . The function of the pre-regulator is guaranteed with the MOSFET IPD30N06S2L-23 of Infineon.

## 8.2 5V Main Supply

The 5V main supply is designed to supply the ECU including micro controller and e.g. other power chips. Out of  $V6V$  a high accurate voltage is provided at the pin  $V5V$ . The pin and the circuit is protected against overload and short circuit. For stabilization and ripple reduction an external buffer capacitor is required. For low drop operation of the regulator the pins  $BATPA$  and  $BATPB$  must be supplied.

## 8.3 Sensor Supply

There are two sensor supplies integrated providing an output voltage based on  $V5V$  as reference. Out of  $V6V$  a high accurate voltage is provided at the pins  $T5V1$  and  $T5V2$ . The pins and the circuits are protected against overload, short circuit and reverse supply back to  $V6V$ . For stabilization and ripple reduction external buffer capacitors are required. For low drop operation of the regulator the pins  $BATPA$  and  $BATPB$  must be supplied.

## 8.4 IO Supply

The TLE8888-1QK provides an IO supply pin  $VDDIO$  for 3.3V and 5V micro controller interfaces. This pin is used for the supply of the output driver and defines the output level of all logical interface pins.

## 8.5 Standby Supply

The TLE8888-1QK integrates a standby supply which is supplied by the pin  $BATSTBY$  and provides a 5V output supply at pin  $V5VSTBY$ . It is not allowed to connect this pin to any other supply.

## 8.6 Charge Pump

There is a charge pump integrated to supply the half bridges out of  $BATPA$  and  $BATPB$ . A capacitor has to be connected on the PCB (between  $CP$  and  $BATPA/BATPB$ ) to buffer the voltage and reduce the ripple. It's not allowed to apply any external load to the pin  $CP$ .

## 8.7 Voltage Monitoring

The TLE8888-1QK provides voltage monitoring of the main ECU supply  $V5V$ , the sensor supplies  $T5V1$  and  $T5V2$  and the battery voltage. In [Chapter 5.2](#) the effect to the status of the TLE8888-1QK is described. All detection thresholds are implemented with a hysteresis and a filter time to suppress disturbances.

The status of the over- and under-voltage detection of  $BAT$ ,  $T5V1$  and  $T5V2$  are available in the diagnosis resistor [Diag0](#) and the bits [BATOV](#), [T1UV](#), [T1OV](#), [T2UV](#) and [T2OV](#).

Under- and over-voltage of  $V5V$  leads to a reset of the micro controller (see [Table 6](#) in [Chapter 5.2](#)). After release of the reset the cause of the reset is available in the status register [OpStat1](#) (bits [V5UVR](#) and [V5OVR](#)).

## 8.8 Electrical Characteristics Power Supply

**Table 23 Electrical Characteristics Power Supply**

$V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_J=-40$  to  $150^\circ C$ , all voltages with respect to GND, positive current flowing into pin, (unless otherwise specified)

1) not subject to production test, specified by design

2) Defined minimum value is needed for regulator stability. Application might need higher value than minimum.

 3) additionally in parallel a capacitance up to  $0.1 \cdot C_{VxV}$  and low ESR is allowed

## 9 Power Stages

In the TLE8888-1QK there are 14 low side power stages, 4 half bridges, 4 push-pull outputs for on board and external ignition driver and 6 push-pull outputs for on board MOSFETs implemented. The 14 low side power stages are designed for various inductive and resistive loads, 4 stages to drive especially injectors, 3 with a higher operating current to drive e.g. O<sub>2</sub>-heaters and 7 stages to drive relays.

For the injector output stages (*OUT1* to *OUT4*) the common enable input *INJEN* and for the ignition outputs the common enable input *IGNEN* are implemented. The half bridges can be used with high or low side load, with active or passive freewheeling or in full bridge configuration.

Figure 28 Block Diagram of the Power stages

**Table 24 Overview Power Stages**

	Type	maximum operation current	Ron	active clamping	Diagnosis in on	Diagnosis in off
<i>OUT1 to OUT4</i>	Low side switch	2.2A	550mΩ	yes	over current (short to battery) over temperature	open load short to GND over temperature

<i>OUT8 to OUT13</i>	5V push pull output	20/-20mA	–	no	at pin DFBx: short to battery  at pin OUTx: over voltage	at pin DFBx: open load short to GND  at pin OUTx: over voltage
<i>OUT14 to OUT20</i>	Low side switch	0.6A	1.5Ω	yes	over current (short to battery) over temperature	open load short to GND over temperature
<i>OUT21 to OUT24</i>	Half bridge	0.6A	2.4Ω	no	over current (short to battery/short to GND) over temperature	open load short to battery/short to GND over temperature
<i>IGN1 to IGN4</i>	5V push pull output	20/-20mA	–	no	short to battery short to GND open load	short to battery

## 9.1 Power Stage Control

The output stages will be controlled either by the MSC/SPI data frame or command frame and the control register **Cont0** to **Cont3** (see [Chapter 14.6](#)) or the direct drive inputs *INI* to *INI2*. The configuration which control mode is active is done in the configuration register **DDConfig0** to **DDConfig3** (see [Chapter 14.5](#)).

A “1” in the control register/data frame bit or a “high” at the direct drive inputs switches on the corresponding output. In [Table 25](#) the assignment of the direct drive inputs to the output stages is shown. The set up is valid for MSC and SPI operation.

The status of the power stages is also affected by the operation state and conditions of the TLE8888-1QK and is described in [Chapter 5](#). All power stages are switched off if a micro channel time out occurs. Description of the effect to the control of the power stages see [Chapter 13.1.1, Downstream Supervisory Functions](#).

**Table 25 Direct Drive Input Assignment to Output Stages**

Input	Output	Note
<i>IN1</i> to <i>IN4</i>	<i>OUT1</i> to <i>OUT4</i>	<b>configuration for direct drive:</b> bits <b>O1DD</b> to <b>O4DD</b> of the configuration register <b>DDConfig0</b>  fix assignment of the inputs to the outputs
<i>IN5</i> to <i>IN8</i>	<i>IGN1</i> to <i>IGN4</i>	<b>configuration for direct drive:</b> bits <b>IGN1DD</b> to <b>IGN4DD</b> of the configuration register <b>DDConfig3</b>  fix assignment of the inputs to the outputs
<i>IN9</i> to <i>IN12</i>	<i>OUT5</i> to <i>OUT24</i>	<b>configuration for direct drive:</b> bits <b>O5DD</b> to <b>O24DD</b> of the configuration registers <b>DDConfig0</b> to <b>DDConfig2</b> <b>assignment of input pins:</b> configuration register <b>InConfig0</b> to <b>InConfig3</b> only 4 of this output stages can be switched directly

All direct drive inputs have implemented a pull down current source to define the input voltage. For a multiple assignment of two direct drive inputs for one output stage (wrong configuration) the output is switched off independent of the status of the direct drive inputs.

## 9.2 Power Stages Enable

To enable the power stages a central output enable bit **OE** is defined. The status of the bit is shown in the status register **OpStat1** and can be set with the command register **CmdOE**. Additionally a dedicated output enable bit for each output is defined (see register **OEConfig0** to **OEConfig3**) to avoid uncontrolled repetitive switching in failure case. These enable bits are reset by the protection function of each channel and block switch on of the channels. The bits could not be set if a protection function is active.

With setting the central enable bit to "1" all dedicated output enable bits are set to "1" (if no protection function is active) and all channels are enabled and can be controlled according their configuration.

With setting the central enable bit to "0" all dedicated output enable bits are set to "0" and all channels are disabled. For the injector channels *OUT1* to *OUT4* the common enable input *INJEN* must be set to "high" and for the ignition outputs *IGN1* to *IGN4* the common enable input *IGNEN* must be set to "high" to enable the channels.

### Procedure to switch on after failure condition occurred:

- Read out of diagnosis bits
- Second read out to verify that the failure conditions are not remaining
- Set of the dedicated output enable bit of the affected channel if the diagnosis bit is not active anymore
- Switch on of the channel

### Switch off during battery over voltage:

To protect the power stages against high energy during freewheeling they are switched off for battery voltages greater than the "**BAT Over Voltage Detection Threshold**" (see **Table 23** in **Chapter 8.8**).

## 9.3 Power Stages Configuration

The power stages can be configured according the configuration bits in the configuration registers **OutConfig0** to **OutConfig5**, **BriConfig0**, **BriConfig1** and **IGNConfig**. The direct drive input configuration is described in **Table 25**.

**Table 26 Configuration Overview Power Stages**

	Configuration	Configuration Register
<i>OUT1</i> to <i>OUT4</i>	<b>over current:</b> current limitation or switch off <b>diagnosis in off:</b> pull down current activated/deactivated	<b>OutConfig0</b>
<i>OUT5</i> to <i>OUT7</i>	<b>over current:</b> current limitation or switch off <b>diagnosis in off:</b> pull down current activated/deactivated	<b>OutConfig1</b>
<i>OUT8</i> to <i>OUT13</i>	at pin DFBx: <b>diagnosis in off:</b> pull down current activated/deactivated <b>diagnosis in on:</b> short to battery detection thresholds	<b>OutConfig2</b> and <b>OutConfig3</b> bits 0 to 3

<i>OUT21</i> to <i>OUT24</i>	<b>mode set up:</b> active or passive freewheeling high or low side switch mode half or full bridge mode delayed switch off mode for <i>OUT21</i>	<b>BriConfig0</b> and <b>BriConfig1</b>
<i>IGN1</i> to <i>IGN4</i>	open load in activation/deactivation open load current setting open load detection time	<b>IGNConfig</b>

#### 9.4 Special Function “Delayed Switch Off” for *OUT17* and *OUT21*

A special set up for the control behavior of *OUT17* and *OUT21* is implemented. With the delayed switch off functionality the outputs are suited to drive loads (e.g. starter relay) which must be on during very low battery voltages even if the micro controller is in reset e.g. due to under-voltage. In this operation conditions all other power stages are normally switched off.

With the bits **O17D** in the configuration register **OutConfig4** and **O21D** in the configuration register **BriConfig1** both outputs can be configured to:

- normal control mode according description in **Chapter 9.1**
- delayed switch off mode

*Note:* For delayed switch off mode *OUT17* and *OUT21* must be configured as controlled by MSC/SPI (bits **O17DD/O21DD** in configuration register **DDConfig2** are set to “0”)

Delayed switch off mode for *OUT21* is only allowed in high or low side switch configuration. Fullbridge configuration is not allowed.

*Note:* The delayed switch off mode keeps the two outputs on for the time  $t_{on,del}$  after an trigger event. With the trigger events in normal control mode the outputs are switched off.

In delayed switch off mode the delayed switch off timer starts with following trigger events:

*Note:* The channel must be on before a trigger event, switch on of all channels during the delayed switch off mode is not possible

- under-voltage of the main supply  $V5V$  is detected
- or over-voltage of the main supply  $V5V$  is detected
- or the MSC time out occurs
- or an active signal ("0") at pin *MON*
- or an active signal ("0") at pin *RST*

With the bit **RDOT** in the command register **Cmd0** the delayed switch off timer is restarted and the on time is increased.

The delayed off mode is terminated with following events:

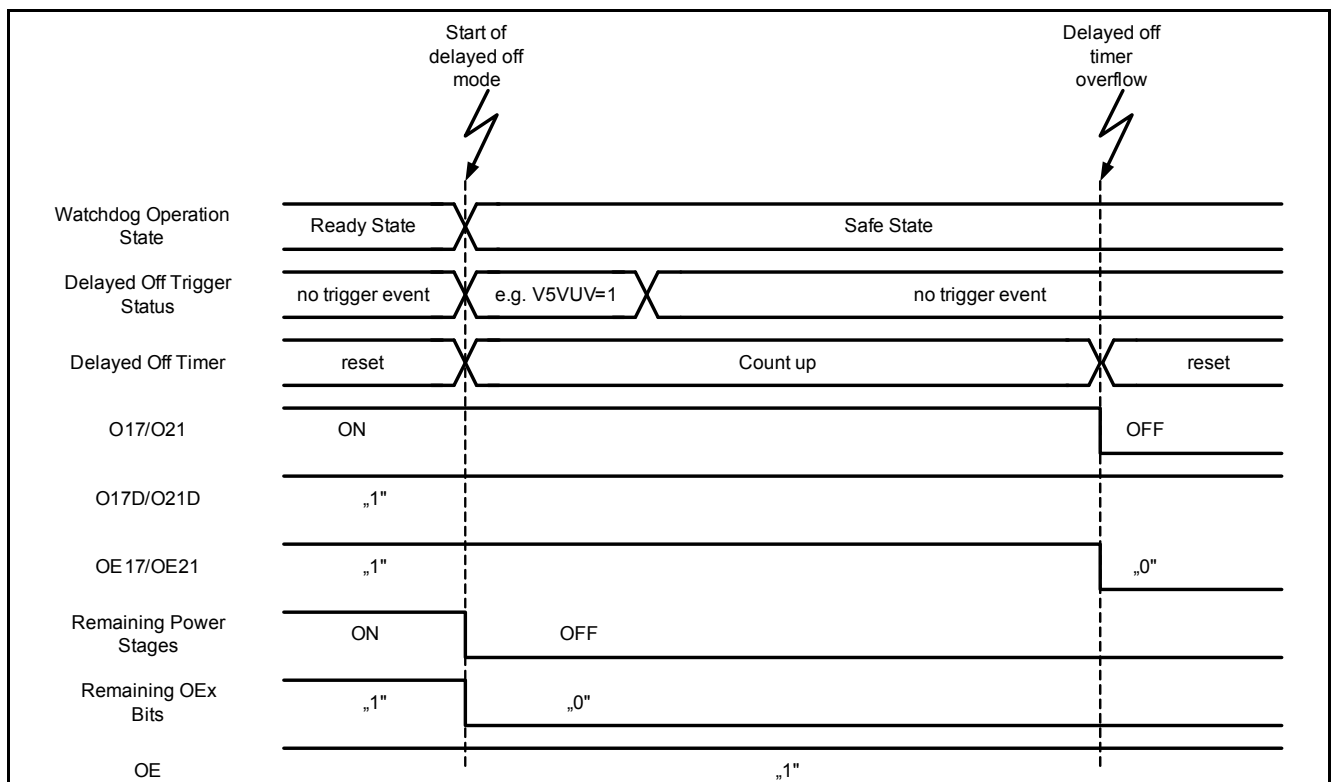

- overflow of delayed off timer
- O17/O21 are switched off with command **CmdOE**, set control register bits **O17ON/O21ON** or the configuration register bits **O17E/O21E** to "0"
- **O17D/O21D** are set to "0"
- Ready State is active and no trigger event is active

The outputs are switched off immediately if an internal power on reset occurs. According to the definition in **Chapter 5.1** if the conditions for a state change to ECU sleep mode are fulfilled the delayed off is terminated and the transition is executed.

Normally the related register bits of *OUT17* and *OUT21* are reset during undervoltage of the main supply  $V5V$  or an active signal ("0") at pin *RST* (definition see **Table 6** and **Table 7** in **Chapter 5.2**). In delayed switch off configuration following register bits are not reset:

- **OE** in status register **OpStat1**
- **O17E**, **O21E** in configuration register **OEConfig2**
- **O17D**, **O17OL**, **O17OC** in configuration register **OutConfig4**
- **O21F**, **O21M** in configuration register **BriConfig0**
- **O21D** in configuration register **BriConfig1**

For illustration in **Figure 29** and **Figure 30** two examples for the delayed switch off mode for are shown.

**Figure 29 Example for Delayed Off Behavior: Overflow of Delayed Off Timer**

Figure 30 Example for Delayed Off Behavior: Stop of Delayed Off Timer with Ready State

## 9.5 Electrical Characteristics Direct Drive Inputs

Table 27 Electrical Characteristics Direct Drive Inputs

$V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_j=-40$  to  $150^\circ C$ , all voltages with respect to GND, positive current flowing into pin, (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
<b>Direct Drive Inputs <i>IN1</i> to <i>IN12</i></b>

Switch On Time in Delayed Switch Off Mode	$t_{on,del}$	400	–	800	ms	–	P_9.5.6

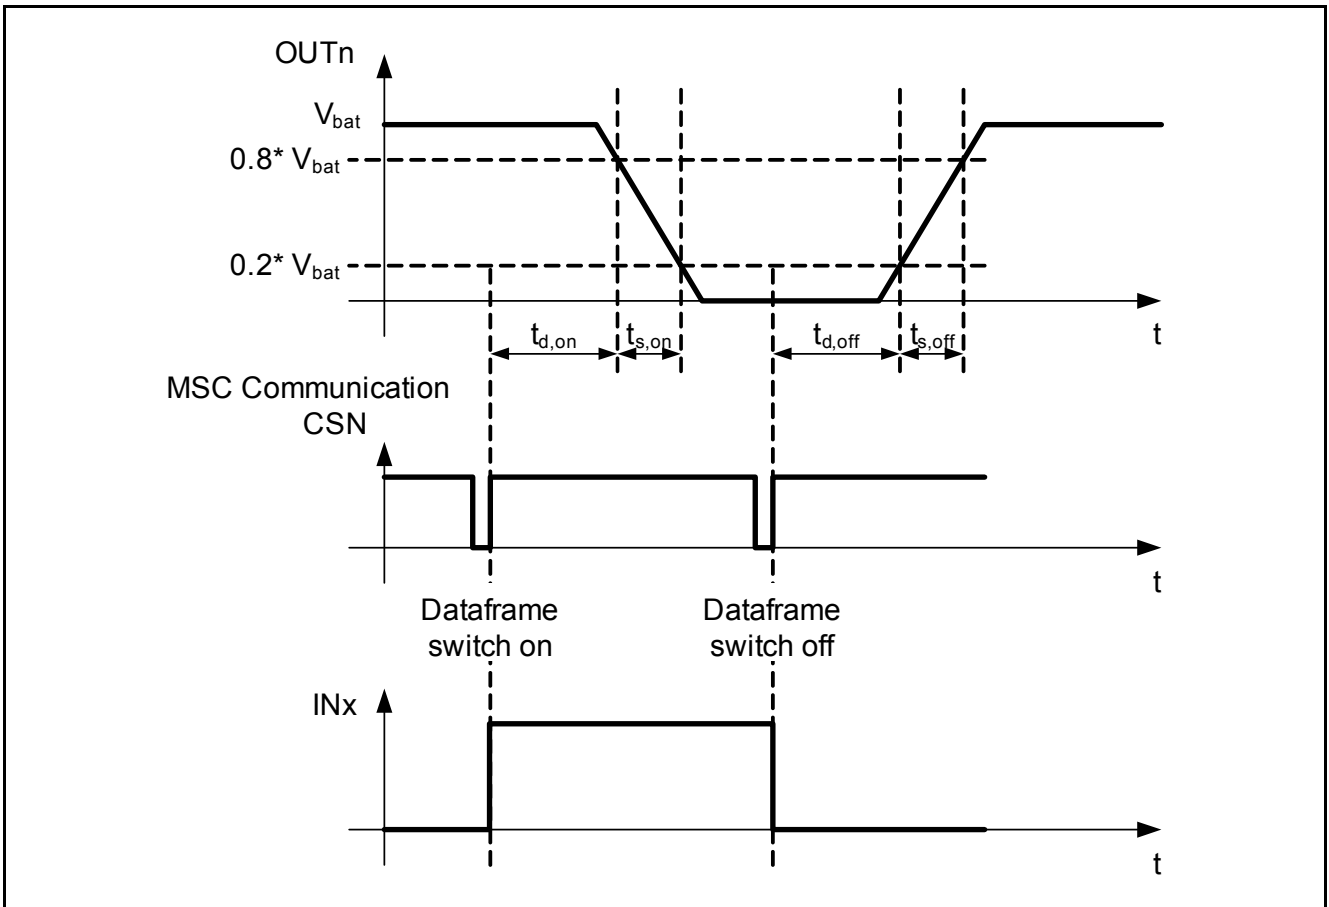

Figure 31 Switching Behavior

## 9.6 Low Side Switches *OUT1* to *OUT7* and *OUT14* to *OUT20*

The low side switches are designed to withstand repetitive clamping events which occurs in automotive applications. The outputs are fully protected and various diagnosis functions are implemented.

They are controlled and enabled like all power stages according the description in [Chapter 9.1](#) and [Chapter 9.2](#). To enable the low side switches *OUT1* to *OUT4* additionally the enable pin *INJEN* must be “high”.

The outputs are fully protected against over current and over temperature and various diagnosis functions are implemented. For the description of the diagnosis function see [Chapter 9.6.2](#).

All power stages are switched off if a micro channel time out occurs. Description of the effect to the control of the power stages see [Chapter 13.1.1, Downstream Supervisory Functions](#).

### 9.6.1 Protection of *OUT1* to *OUT7* and *OUT14* to *OUT20*

The outputs are fully protected against over current and over temperature.

The current protection of the power stages *OUT1* to *OUT7* and *OUT14* to *OUT20* can be configured to current limitation or switch off in case of over current (configuration register [OutConfig0](#), [OutConfig1](#), [OutConfig3](#) to [OutConfig5](#) bits [O10C](#) to [O70C](#) and [O140C](#) to [O200C](#)). In failure case (e.g. short to battery) the output current of the low side switches are always limited and an over current condition is detected if the over current signal is valid longer than the “[Over-current Detection Filter Time](#)”. With the detection the corresponding diagnosis bits are set according the priority shown in [Table 28](#) and for switch off configuration additionally the output is switched off.

To cover all failure conditions the over temperature protection is implemented. Especially for the over current limitation configuration the over temperature is the only protection function against over load. After exceeding the temperature threshold the outputs are switched off till the temperature is decreased by the “[Over Temperature Hysteresis](#)”.

For the procedure to switch on an affected channel after failure condition see [Chapter 9.2](#).

### 9.6.2 Diagnosis of *OUT1* to *OUT7* and *OUT14* to *OUT20*

For the low side outputs various diagnosis function are implemented. For short to battery in on diagnosis the protection function over current and over temperature are used to set the diagnosis information and for open load and short to GND (SCG) in off a special circuit is implemented.

To detect the open load/short to GND a push pull circuits is active which leads to the function of the voltage and currents of the outputs shown in [Figure 32](#). With the defined detection threshold the load condition can be detected.

With the off signal of the output stage the open load/short to GND detection circuit is enabled. To suppress disturbances the output of the detection circuit is stored in the diagnosis register [OutDiag0](#) to [OutDiag4](#) after the “[Diagnosis Filter Time for open load and short to GND in off](#)”  $t_{diag,f}$  and according the priority shown in [Table 28](#). With the readout of the diagnosis register the content is updated to the actual diagnosis.

For the outputs *OUT1* to *OUT7* and *OUT14* to *OUT17* the diagnosis pull down current of the open load/short to GND in off detection could be switched off (see configuration register [OutConfig1](#) to [OutConfig4](#)). With deactivated pull down current open load in off detection is not active and the diagnosis information  $10_B$  will never occur and is deactivated. With deactivated pull down current the short to GND detection is active.

For the outputs *OUT18* to *OUT20* the diagnosis pull up and down currents could be switched off (bits [O18OL](#) and [O20OL](#) in configuration register [OutConfig5](#)). In this case no diagnosis information in off is active and the bits [O18DIAG1](#), [O19DIAG1](#) and [O20DIAG1](#) are “0”.

In [Figure 32](#) the behavior open load/short to GND in off detection of the output current as a function of the output voltage is shown.

Figure 32 Output behavior with active diagnosis in off

Table 28 Description of Diagnosis Information

OnDIAG[1:0]	Priority (1 = highest priority)	Description
00	4	no failure
01	1	short circuit to battery (over current) or over temperature
10	2	open load in off <sup>1) 2)</sup>
11	3	short circuit to ground in off <sup>2)</sup>

1) no open load in off detection with deactivated pull down current

2)no open load and short to GND in off signalization for *OUT18* to *OUT20* if pull up and down currents are switched off

### 9.6.3 Electrical Characteristics Low Side Switches *OUT1* to *OUT7* and *OUT14* to *OUT20*

Table 29 Electrical Characteristics Low Side Switches *OUT1* to *OUT7* and *OUT14* to *OUT20*

 $V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_j=-40$  to  $150^\circ\text{C}$ , all voltages with respect to GND, positive current flowing into pin, (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
Switch Off Time	$t_{s,off}$	1.1	–	5.6	$\mu\text{s}$	$V_{OUTn}=13.5V$ , $I_{OUTn}=0.3A$ , resistive load <sup>3)</sup>	P_9.6.40
Delayed Off Time after trigger event for <i>OUT17</i>	$t_{off,del}$	400	–	800	ms		P_9.6.41

**Diagnosis *OUT1* to 7 and *OUT14* to 20**

Over Temperature Switch Off Threshold	$T_{OUTn,ot}$	150	–	200	$^\circ\text{C}$	1)	P_9.6.42
Over Temperature Hysteresis	$T_{OUTn,ot,hys}$	–	10	–	$^\circ\text{C}$	1)	P_9.6.43
Open Load in Off Detection Threshold	$V_{ol}$	$V5V-0.15$	$V5V$	$V5V+0.15$	V		P_9.6.44
Short to GND in Off Detection Threshold	$V_{scg}$	$0.6^*V5V-0.15$	$0.6^*V5V$	$0.6^*V5V+0.15$	V		P_9.6.45
Diagnosis Pull Up Current	$I_{diag,pu}$	-270	–	-150	$\mu\text{A}$	$V_{OUTn}=0V$ , $V_{IGNx}\geq 0V$	P_9.6.46
Diagnosis Pull Down Current	$I_{diag,pd}$	280	–	500	$\mu\text{A}$	$V_{ol}<V_{OUTn}<V_{BAT}$ , $V_{IGNx}\geq 0V$	P_9.6.47
Diagnosis Filter Time for open load and short to GND in off	$t_{diag,f}$	60	–	135	$\mu\text{s}$		P_9.6.48

**Direct Drive Inputs *INJEN***

Low Level Input Voltage	$V_{IN,l}$	-0.3	–	0.9	V		P_9.6.49
High Level Input Voltage	$V_{IN,h}$	2	–	$V_{VDDIO}$	V		P_9.6.50
Input Voltage Hysteresis	$V_{IN,hys}$	50	200	–	mV		P_9.6.51
Pull Down Current	$I_{IN,pd}$	25	–	100	$\mu\text{A}$	$V_{IN}=V_{VDDIO}$	P_9.6.52
Pull Down Current	$I_{IN,pd}$	2.4	–	–	$\mu\text{A}$	$V_{IN}=0.6V$	P_9.6.53

1) Parameter is not subject of production test, specified by design

 2) additionally diagnosis currents are active in operation mode; exception *OUT18* to *OUT20* in diagnosis current switch off configuration

 3) see [Figure 31](#)

## 9.7 Half Bridges *OUT21* to *OUT24*

The TLE8888-1QK integrates 4 half bridges which can be used as half bridge, full bridge, low side power stage or high side power stage. They are fully protected against overload and over-temperature and diagnosis fits to the chosen setup of the load. For the description of the diagnosis function see [Chapter 9.7.2](#).

They are controlled and enabled like all power stages according the description in [Chapter 9.1](#) and [Chapter 9.2](#). In [Table 30](#) the effect of [O21E](#) to [O24E](#) and [O21ON](#) to [O24ON](#) to the high side and low side switch of the half bridge is shown.

The half bridges can be configured via MSC/SPI for high or low side loads (setup see [Figure 33](#)) and for passive or active freewheeling (freewheeling is done with bulk diode or actively with switching on the freewheeling path). In [Table 30](#) the configuration is shown. With the bits [O21M](#) to [O24M](#) of the configuration register [BriConfig0](#) the switching mode is defined. With this configuration the low or the high side transistor is defined to switch on the load. For low side switch mode the load is connected to the battery, for high side switch mode the load is connected to GND (see [Figure 33](#)). With the bits [O21F](#) to [O24F](#) of the configuration register [BriConfig0](#) the freewheeling behavior is defined. The freewheeling is done for low side switch mode with the high side transistors. For passive freewheeling the bulk diode is used and the freewheeling transistor is always off. For the active freewheeling mode the freewheeling transistor is on during an off signal. This is the so called half bridge mode. The alternate switching of the high side and low side switch is done with a break before make phase. The definition of the switching mode is important for the correct diagnosis in off (see [Chapter 9.7.2](#)). The bits [FB1E](#) and [FB2E](#) (full bridge enable) are only used for the diagnosis in off for full bridge set up. [FB1E](#) = "1" is used for loads connected between *OUT21* and *OUT22*. [FB2E](#) = "1" is used for loads connected between *OUT23* and *OUT24*. The diagnosis in off setup is changed to the special situation of full bridge mode. The setting with [O21M](#) to [O24M](#) and [O21F](#) to [O24F](#) are valid.

**Note:** for full bridge set up the same set up for the two half bridges is recommended!

**Table 30 Configuration of the Half Bridge**

1) n=21 to 24 for the selected half bridge channel

2) setup definition see [Figure 33](#)

**Figure 33 Load setups for half and full bridge mode**

### 9.7.1 Protection of Half Bridges *OUT21* to *OUT24*

The half bridge outputs are fully protected against over-current and over-temperature.

In failure case (e.g. short to GND) the affected transistor is switched off after the “**Over-current Switch Off Filter Time**” and the diagnosis bit is set. The half bridge output is high ohmic (tristate).

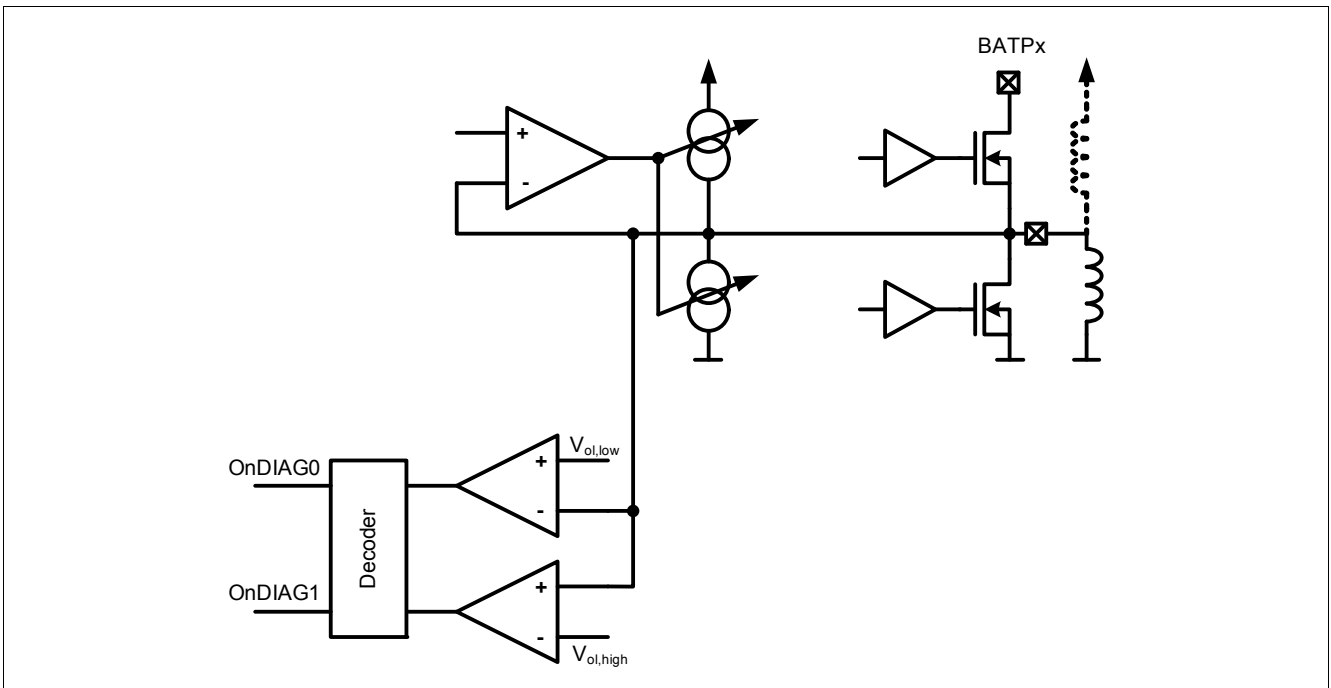

To cover all failure conditions the over temperature protection is implemented. After exceeding the temperature threshold the half bridge outputs are switched off till the temperature is decreased by the “**Over Temperature**”

Hysteresis”.

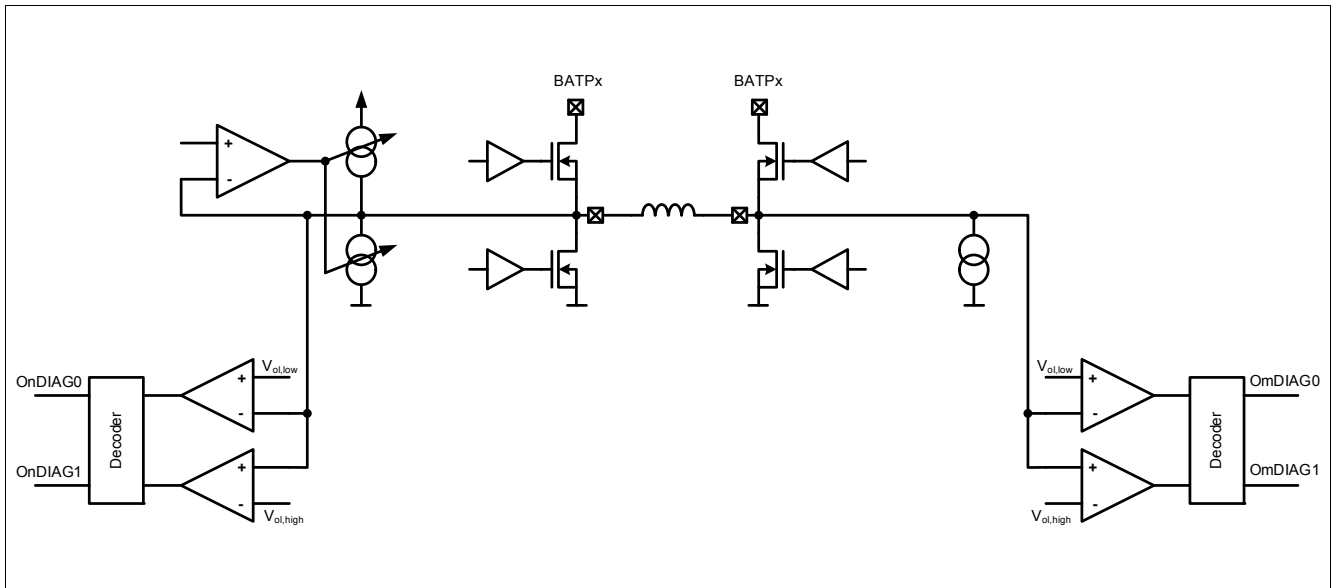

For the procedure to switch on an affected channel after failure condition see [Chapter 9.2](#).

### 9.7.2 Diagnosis of Half Bridges *OUT21* to *OUT24*

For the half bridge outputs various diagnosis function are implemented. For short to battery and short to GND in on diagnosis the protection function over current is used (diagnosis bits **O21OC** to **O24OC** in diagnosis register **BriDiag1**). Over temperature is signalized with the diagnosis bits **B1OT** and **B2OT** in diagnosis register **BriDiag1**. For open load and short to GND (SCG) in off a special circuit is implemented. The diagnosis bits **O21DIA** to **O24DIA** in diagnosis register **BriDiag0** are set according the setup of the channels and according the priority shown in [Table 31](#).

**Figure 34** Open Load and Short to GND/Battery Detection Circuit for Half Bridge Configuration (Low or High Side Load)

**Figure 35 Open Load and Short to GND/Battery Detection Circuit for Full Bridge Configuration**

In [Figure 36](#) and [Figure 37](#) the behavior of the output current as a function of the output voltage in the different configurations are shown.

The detection in off for open load is the same for both settings but for the short detection there is a difference for low side and high side switch mode.

- High side switch mode: short to battery detection in off
- Low side switch mode: short to GND detection in off

**Figure 36 Output Behavior in Off for Low Side Switch Configuration with Open Load and Short to GND Detection**

**Figure 37 Output Behavior in Off for High Side Switch Configuration with Open Load and Short to Battery Detection**

**Figure 38 Output Behavior in Off for Full Bridge Mode Configuration**

The detection is active if the high side and the low side switch are off and the diagnosis activation timer  $t_{br,diag,act}$  starts counting. For activation of the open load in off detection in active freewheeling configuration the half bridge must be disabled by setting the bits **O21E** to **O24E** of configuration register **OEConfig2** to “low”, for passive freewheeling a normal off signal (**IN9** to **IN12** or **O21ON** to **O24ON** in control register **Cont2** is set to “low”) is sufficient. For full bridge mode both half bridges must be off or disabled regarding the setting of the half bridge. After the **Bridge Diagnosis Activation Time**  $t_{br,diag,act}$  the output of the detection circuit is stored in the diagnosis register **BriDiag0** according the priority shown in **Table 31**. After activation of the open load in off detection a filter time  $t_{br,diag,f}$  to suppress disturbances is implemented. The diagnosis register bits are set after the specified filter times. With the readout of the diagnosis register the content is updated to the actual diagnosis.

In **Table 31** the definition of the diagnosis bits for single switch usage is defined, in **Table 32** the definition for full bridge mode.

*Note: especially for full bridge mode it is recommended to read out the diagnosis register twice due to transition states and possible misleading diagnosis register entries*

**Table 31 Description of Diagnosis Information Single Switch Usage**

OnDIAG[1:0] <sup>1)</sup>	Priority (1 = highest priority)	High Side Switch Mode	Low Side Switch Mode
00	3	no failure	no failure
01	2	open load in off	n.a.
10	2	n.a.	open load in off
11	1	short circuit to battery in off	short circuit to ground in off

1) n from 21 to 24

*Note: For high side switch mode (low side load) after start up there will be a short to ground detection before the output is configured to high side load and the diagnosis bits are set to "11". This detection is not right and it is recommended to read out the diagnosis registers twice after start up to avoid wrong diagnosis information.*

2) see [Figure 31](#) for timing definition

3) not subject to production test, specified by design

## 9.8 Push Pull Stages *OUT8* to *OUT13* and *DFB8* to *DFB13*

These 5V push pull stages are designed for driving on-board MOSFET's. The outputs are fully protected and various diagnosis functions are implemented.

They are controlled and enabled like all power stages according the description in [Chapter 9.1](#) and [Chapter 9.2](#). In off ("0" in control register or "low" at the configured direct drive input pin) the low side transistor of the push/pull stage is on and forces a "low voltage level at the pin.

### 9.8.1 Protection of *OUT8* to *OUT13*

There are functions implemented to detect short to battery at the external MOSFET and to protect the driver outputs.

For the short to battery detection feedback pins *DFB8* to *DFB13* are implemented to sense the voltage at the drain of the external MOSFET. The short to battery detection in on is done by comparing the voltage level of the drain feedback pins with the short to bat detection threshold.

A short is detected after the "[Short to Battery Detection Filter Time](#)". In case of short to battery the output is switched off and the corresponding diagnosis bits in the diagnosis register [OutDiag1](#) to [OutDiag3](#) are set according the priority shown in [Table 34](#). There are four different thresholds, "[Short to Battery Detection Threshold in On 1](#)" to "[Short to Battery Detection Threshold in On 4](#)", implemented so that the detection threshold can be adapted to the used MOSFET. The diagnosis of the push pull stages can be set in three groups. The configuration is done with the bits [PP0D](#) to [PP2D](#) in the configuration register [OutConfig2](#) and [OutConfig3](#). The protection of the driver output pins is done by comparing the output voltage on the pins *OUT8* to *OUT13* with the "[Over Voltage Detection Threshold](#)". An over voltage (e.g. short to battery) is detected after the "[Over Voltage Diagnosis Filter Time](#)" and the corresponding diagnosis bits in the diagnosis register [PPOVDiag](#) is set. In case of over voltage high and low side transistors of the push pull driver are switched off (high ohmic state).

### 9.8.2 Diagnosis of *OUT8* to *OUT13*

For the push pull stages *OUT8* to *OUT13* various diagnosis functions for the external MOSFETs are implemented. The open load, short to ground in off and short to battery in on detection is done via the drain feedback *DFB8* to *DFB13*. The diagnosis pull down current of the open load/short to ground in off detection can be switched off (see configuration register [OutConfig2](#)). With deactivated pull down current open load in off detection is not active and the diagnosis information of  $OnDIAG[1:0]=10_B$  will never occur. With deactivated pull down current the short to ground detection is active.

In [Figure 39](#) the behavior of the output current as a function of the output voltage is shown.

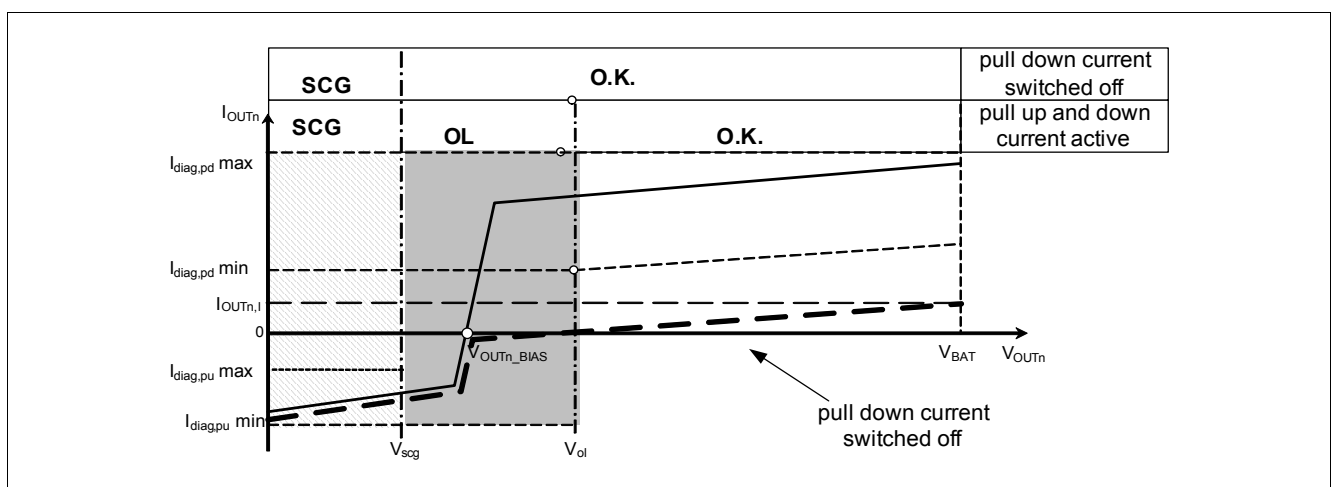

Figure 39 Output behavior in off with open load and short to GND detection of *DFB8* to *DFB13*

Whenever the push pull stages are off the open load/short to GND detection circuit is enabled. To suppress disturbances the output of the detection circuit is stored in the diagnosis register **OutDiag1** to **OutDiag3** after the **Diagnosis Filter Time for Open Load and Short to GND in Off Detection**  $t_{diag,f}$  and according to the priority shown in **Table 34**. With the readout of the diagnosis register the content is updated to the actual diagnosis.

**Table 34 Description of Diagnosis Information (DFB8 to DFB13)**

OnDIAG[1:0]	Priority (1 = highest priority)	Description
00	4	no failure
01	1	short circuit to battery
10	2	open load in off <sup>1)</sup>
11	3	short circuit to ground in off

1) no open load in off detection with deactivated pull down current

### 9.8.3 Electrical Characteristics Push Pull Stages *OUT8* to *OUT13*

**Table 35 Electrical Characteristics Push Pull Stages *OUT8* to *OUT13***

Stages on or off,  $V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_j=-40$  to  $150^\circ C$ , all voltages with respect to GND, positive current flowing into pin, (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.

## 9.9 Push Pull Stages *IGN1* to *IGN4*

The *IGN1* to *IGN4* are 5V push pull stages for on- and off-board ignition power stages (e.g. with IGBT's, darlington transistors). For off board ignition power stages the outputs *IGN1* to *IGN4* are equipped with a back supply suppression (in case of a short circuit from *IGN1* to *IGN4* to battery there is no parasitic current flow back to 5V).

They are controlled and enabled like all power stages according the description in [Chapter 9.1](#) and [Chapter 9.2](#). Additionally a “high” at the pin *IGNEN* is needed to enable the outputs. In off (“0” in control register or “low” at the configured direct drive input pin or *IGNEN* is “low”) the low side transistor of the push/pull stage is on and forces a “low voltage level at the pin.

The outputs are fully protected and various diagnosis functions are implemented.

### 9.9.1 Protection of *IGN1* to *IGN4*

The protection of the outputs is done by detecting short to battery and short to ground. This is done by comparing the output voltage level with the “[Short to Battery Detection Threshold](#) and [Short to Ground Detection Threshold](#)”. To suppress disturbances the output signal of the short to GND and short to battery detection circuit is stored in the diagnosis register *IgnDiag* after the “[Diagnosis Filter Time for Short to GND and Battery Detection](#)”  $t_{diag,f,sc}$  and according the priority shown in [Table 36](#).

During detected short to GND the output is switched off (low side transistor of push/pull stage is on), during detected short to battery the output is high ohmic (tristate).

The short to battery detection is always active. The short to ground detection is enabled with the on signal of the output stage.

Additionally an over temperature protection is implemented. There is one common sensor for *IGN1* and *IGN2* and one for *IGN3* and *IGN4*.

### 9.9.2 Diagnosis of *IGN1* to *IGN4*

An open load detection during the switch on phase is implemented and can be enabled with the bit *IOLA* in the configuration register *IGNConfig*. In [Figure 40](#) the detection principle is shown. When the open load detection in on is enabled, first the output is pulled up by a defined current, which is set by the bits *IOLI* in the configuration register *IGNConfig*.

The output voltage, which is passed to the detection circuit, is filtered (“[Diagnosis Filter Time for Open Load Detection](#)”) to suppress disturbances. After the open load time (“[Open Load Time 1](#)” to “[Open Load Time 4](#)” selected in configuration register *IGNConfig* bits *IOLT*) the filtered output is compared with the [Open Load](#)

**Detection Threshold  $V_{ol}$ .** The diagnosis register **IgnDiag** is set if the filtered output is higher than the **Open Load Detection Threshold** and the output is fully switched on.

The failures are stored in the diagnosis register according the priority shown in **Table 36** with “1” is the highest priority. With the readout of the diagnosis register **IgnDiag** the content is updated to the actual diagnosis.

**Table 36 Description of Diagnosis Information (IGN1 to IGN4)**

IGNnDIAG[1:0]	Priority (1 = highest priority)	Description
00	4	no failure
01	1	short circuit to battery or over temperature
10	2	open load
11	3	short circuit to ground in on

**Figure 40 Ignition Output Open Load Detection**

### 9.9.3 Electrical Characteristics Push Pull Stages *IGN1* to *IGN4*

**Table 37 Electrical Characteristics Push Pull Stages**

Stages on or off,  $V_S=13.5V$ ,  $V_{VSV}=5V$ ,  $T_j=-40$  to  $150^{\circ}C$ , all voltages with respect to GND, positive current flowing into pin, (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
<b>IGN1...4, n=1 to 4</b>							
High Level Output Voltage	$V_{IGNn,h}$	4.35	–	–	V	$I_{IGNn}=-15mA$ ,	P_9.9.1
Low Level Output Voltage	$V_{IGNn,l}$	–	–	0.6	V	$I_{IGNn}=5mA$	P_9.9.2
Pull up current	$I_{IGNn,pu}$	–	–	-20	mA	$V_{IGNn}=0V$ , IGNn on	P_9.9.3

**Table 37 Electrical Characteristics Push Pull Stages (cont'd)**

Stages on or off,  $V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_j=-40$  to  $150^\circ C$ , all voltages with respect to GND, positive current flowing into pin, (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number

## 10 VR and Hall Sensor Interface

The variable reluctance (VR) sensor interface converts an output signal of a VR sensor into a push-pull logic level signal suited for micro controller input ports. To achieve the best accuracy for the positive and the negative edge of the  $VR_{OUT}$  signal the switching point is the zero crossing. For robustness against disturbances the next zero crossing is enabled only if a signal peak (minimum or maximum of the signal) is detected. The amplitude of the VR sensor signal is limited by an internal clamping circuit to avoid damage of the device due to over voltage caused by the VR sensor signal.

There are three operation modes for VR sensor applications and one Hall sensor mode implemented. The manual VR sensor mode with static setup of the detection parameter under control of the micro controller via MSC/SPI and an auto mode with an adaptive algorithm to ensure best detection performance. The semi auto mode is less accurate than the auto mode.

The diagnosis VR sensor interface setup could be done by measuring the voltage between the two input pins during diagnosis mode. Additionally three diagnosis bits for short to battery, short to GND and open load (directly at the pins) are available.

Figure 41 VR Sensor Interface Block diagram

### 10.1 Signal Detection

The signal detection for Hall sensor mode is a comparator with the switching threshold  $V_{VRIN1,th,hall}$  and the hysteresis  $V_{VRIN1,hys,hall}$ . The detection of the VR signal consist of the zero crossing detection, peak detection and the output filter. At the input there is a clamping circuit between the pins  $VRIN1$  and  $VRIN2$  suited to clamp the maximum current of VR sensors.

The zero crossing detection ensures that the influence of the input signal slope is eliminated for both edges. To avoid disturbances due to the floating input signal a middle voltage is applied with the integrated load resistance. The clamping circuit between the pins  $VRIN1$  and  $VRIN2$  clamps the input voltage in both direction to protect the input structures. The clamping is suited for VR sensors with a maximum output current of  $DI_{VR,clamp}$  (see Table 38).

The peak detection is done by measuring the voltage difference by the analog to digital converter and the detection of the slope of the input signal. If the gradient of the slope changes the sign the next zero crossing detection is enabled. The detection of the sign is done by comparing the absolute value of the signal with the peak detection

threshold ( $V_{VR,peak,min,1}$  to  $V_{VR,peak,min,4}$  according setup). A sign change is only valid if the absolute value of the signal is larger than peak detection threshold ( $V_{VR,peak,min,1}$  to  $V_{VR,peak,min,4}$  according setup) for a time longer than the peak detection time  $t_{VR,peak,min,1}$  to  $t_{VR,peak,min,2}$  according setup (see [Figure 42](#)).

**Figure 42** Timing Characteristics of the VR Sensor Interface

The output filter is implemented for all operation modes to suppress disturbances with high frequencies. The function is shown in [Figure 43](#). The output signal  $V_{ROUT}$  is filtered with the time  $t_{of,1}$ . The output signal of the internal zero crossing detection must be stable for a time longer than  $t_{of,1}$ .

**Figure 43** Output Filter Behavior

Following parameters could be set by MSC/SPI communication:

- peak detection threshold  $V_{VR,peak,min,1}$  to  $V_{VR,peak,min,4}$  with the bits **VRSPV** in the configuration register **VRSCfg0**
- peak detection time  $t_{VR,peak,min,1}$  to  $t_{VR,peak,min,2}$  with the bit **VRSPt** in the configuration register **VRSCfg0**
- output filter time  $t_{of,1}$  to  $t_{of,4}$  with the bits **VRSF** in the configuration register **VRSCfg0**

## 10.2 Detection Modes

The TLE8888-1QK integrates four detection modes:

- auto detection mode for VR sensor signals
- manual detection mode for VR sensor signals
- semi auto detection mode for VR sensor signals
- detection mode for Hall sensor signals

To select the various detection modes the bits **VRSM** in the configuration register **VRSCConfig1** must be set.

**Auto detection mode for VR sensor signals:** In the auto detection mode an algorithm is setting all parameters to the optimal values to achieve the best detection behavior. The peak detection time is set due to the actual speed value, the peak detection threshold is set due to the level of the previous peaks. The output filter time ( $t_{of,1}$  to  $t_{of,4}$ ) is set by the micro controller independently to increase the robustness against short disturbances at the inputs. Write access to the registers bits of **VRSPT** and **VRSPV** are ignored in auto detection mode.

**Semi auto detection mode for VR sensor signals:** The algorithm of the semi auto mode is based on less number of measurement information as the auto detection mode. This leads to a simpler implementation of the detection algorithm. The output filter time ( $t_{of,1}$  to  $t_{of,4}$ ) is set by the micro controller independently to increase the robustness against short disturbances at the inputs. Write access to the registers bits of **VRSPT** and **VRSPV** are ignored in semi auto detection mode.

**Manual detection mode for VR sensor signals:** In the manual detection mode the micro controller has the full control of all parameters of the detection and the algorithm of the auto detection modes are disabled. The settings are done via the MSC/SPI interface.

**Detection mode for Hall sensor signals:** For the Hall sensor mode the pin *VRIN2* is forced internally to the switching threshold  $V_{VRIN1,th,hall}$ . The detection principle is a comparator with hysteresis. Write access to the registers bits of **VRSPT** and **VRSPV** are ignored in the detection mode for Hall sensor signals. The diagnosis is disabled. With this set up the number of external devices is reduced (see [Chapter 17.2](#)).

*Note: Switching between the different configuration must be avoided with active signals at the inputs *VRIN1* and *VRIN2*.*

## 10.3 Diagnosis for VR Sensor Signal Detection Modes

The TLE8888-1QK integrates three different diagnosis modes for the VR sensor interface:

- **short to GND/short to battery diagnosis mode:** detection of short to GND or short to battery directly at pins *VRIN1* and *VRIN2*
- **open load diagnosis mode:** detection of open load directly at pins *VRIN1* and *VRIN2*
- **ADC measurement mode:** measurement of the voltage between the pins *VRIN1* and *VRIN2*

The modes are defined in the configuration register **VRSCConfig1** with the bits **VRSDIAGM**.

The diagnosis of the VR sensor is done by activating the diagnosis mode with the bits **VRSDIAGM** in the configuration register **VRSCConfig1** and starting diagnosis measurement with the bit **VDIAGS** in the command register **Cmd0**. With the activation of the VRS diagnosis mode at *VRIN1* a pull up current source to the internal supply and at *VRIN2* a pull down current source is applied (current configuration with bits **VRSI\_SC** for short to GND/short to battery diagnosis mode, **VRSI\_OL** for open load diagnosis mode and **VRSI\_ADC** for ADC measurement mode in the configuration registers **VRSCConfig1** and **VRSCConfig2**). To avoid bad influence of the time constants of the external circuitry the timing of the measurement is controlled by the micro controller. The sequence is shown in [Figure 44](#).

The end of the diagnosis procedure triggered by the start command is signaled by the correspondent data valid bits **VRSDV\_SC** (short to GND and short to battery diagnosis mode), **VRSDV\_OL** (open load diagnosis mode) in diagnosis register **VRSDiag0** and **VRSDV\_ADC** (ADC measurement mode) in the diagnosis register **VRSDiag1**. For the detection thresholds see parameter **Short to GND detection threshold**, **Short to battery detection**

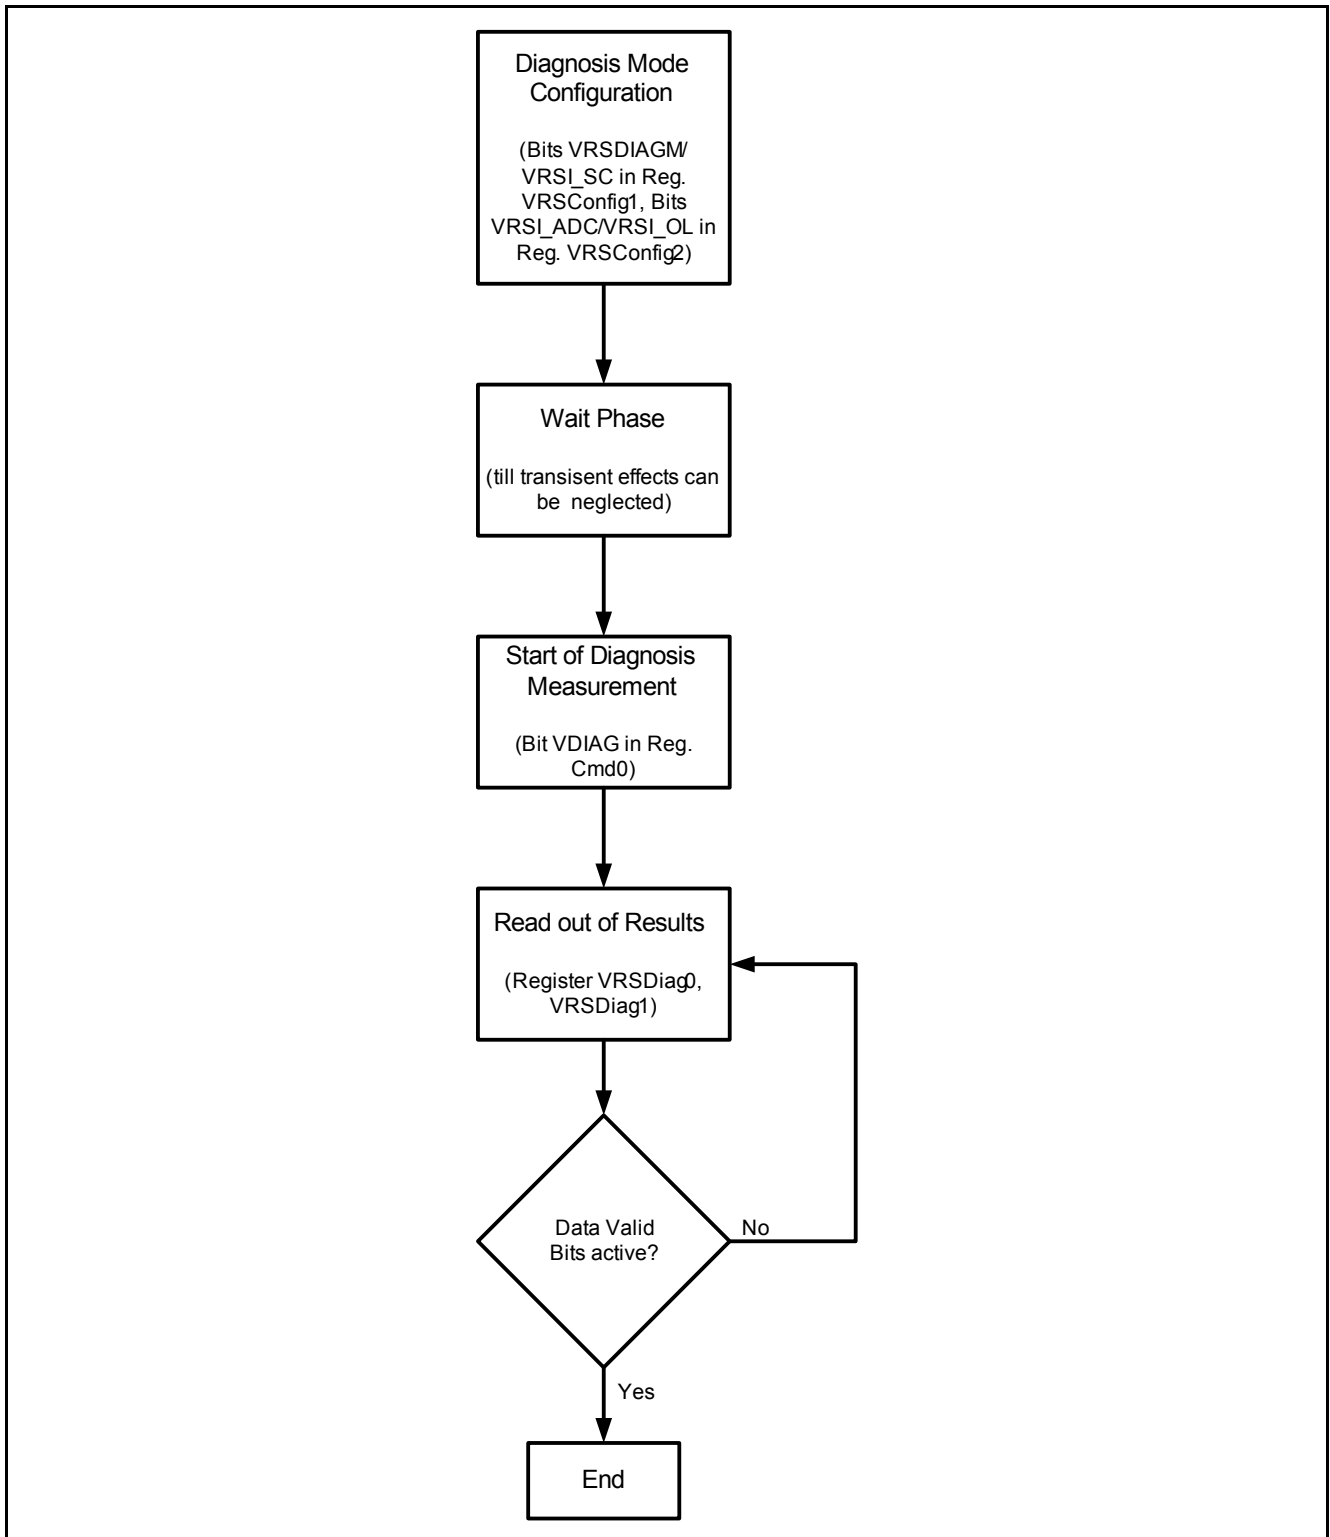

**threshold** and **Open load detection threshold**. The output of the ADC measurement is defined by the parameter **ADC measurement gain** and **ADC measurement offset**.

The result of the diagnosis is available in the diagnosis register **VRSDiag0** with the bits **VRSG** (short to GND detection), **VRSB** (short to battery detection) and **VRSOL** (open load detection directly at the pins). The digital value of the ADC measurement is available in the register **VRSDiag1** with the bits **VRSD**. This ADC value can be used by the micro controller to define additional error detection conditions different to the defined short to GND, short to battery and open load thresholds.

The data valid bits are reset with start of the corresponding diagnosis or with the readout of the register.

*Note: In detection mode for Hall sensor signals the diagnosis is deactivated and the values of **VRSDIAGM** and **VRSI\_SC** in the register **VRSCConfig1**, **VRSI\_ADC** and **VRSI\_OL** in register **VRSCConfig2** and the start command **VDIAGS** in the register **Cmd0** are ignored.*

**Figure 44 VRS Flow Chart**

For the measurement the internal circuits are changed. In [Figure 45](#), [Figure 46](#) and [Figure 47](#) the block diagram of the different setups are shown.

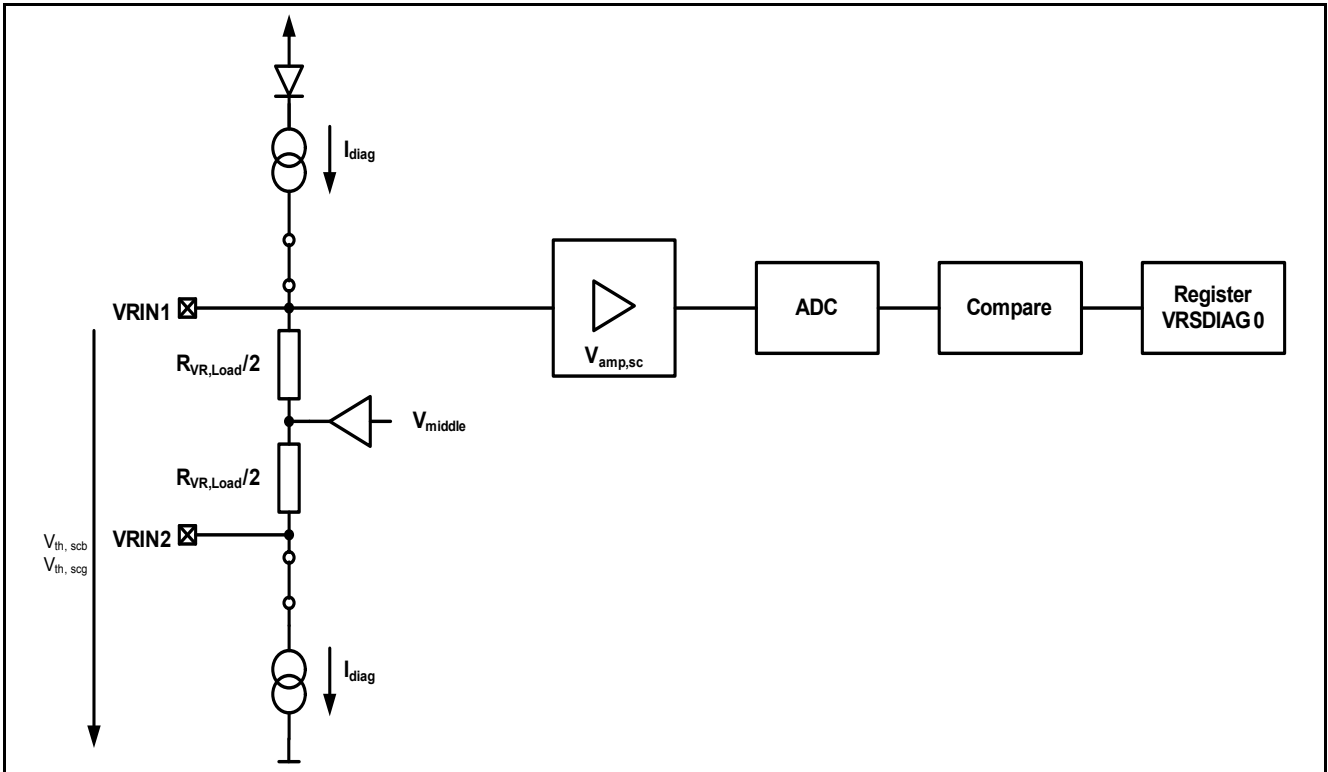

Figure 45 VRS Diagnosis Block Diagram for Short to GND and Short to Battery Measurement

## 11 Local Interconnect Network (LIN)

The LIN interface is designed for in-vehicle networks using data transmission up to 20kbit/s. The implementation of the physical layer is according to LIN specification revision 2.1 for slave nodes and is compatible with lower versions like revision 2.0 and 1.3<sup>1)</sup>. *LINTX* is the transmit-data input from the micro controller, *LINIO* is the bidirectional LIN bus signal and *LINRX* is the receive-data output to the micro controller. The transmitted data stream at *LINTX* is converted to the LIN bus signal at *LINIO*. *LINRX* reflects the received data at *LINIO* with a logic signal suited for 3.3V and 5V micro controller interfaces.

The detection thresholds at *LINIO* are related to the power supply *BATPA*<sup>2)</sup>.

The LIN interface of the TLE8888-1QK is compatible to the physical layer definition of the K-Line (ISO 9141) standard. For K-Line operation no additional settings are necessary.

A flash mode for high speed operation can be selected with the communication interface (MSC or SPI). There is no bus wake up function implemented.

**Figure 48 Local Interconnect Network (LIN) Slave Node**

The LIN interface in the TLE8888-1QK is implemented according the requirements of the standard for slave nodes. For master setup an external pull up resistor (typ. 1kΩ, see definition in LIN specification) and a diode must be connected to *LINIO* and *BATPA* on the ECU (see [Figure 49](#)).

1) see LIN specification revision 2.1 chapter 6.2

2) *BATPA* is identical to the internal supply voltage  $V_{SUP}$  defined in LIN specification revision 2.1

Figure 49 Local Interconnect Network (LIN) Master Node

## 11.1 Operation Modes

The interface can be configured for three operation modes:

- **LIN/K-Line Mode:** operation according LIN specification revision 2.1 with a maximum speed of 20kbit/s and K-Line standard ISO 9141
- **Receive Only Mode:** transmission of data is disabled
- **Flash Mode:** operation up to 115 kbit/s is possible, slope control and current limitation are deactivated

The selection of the modes is done with setting the bits **LIN** in the register **ComConfig1** via communication interface (MSC or SPI). The operation mode after power on reset is defined by reset value of the register.

## 11.2 Failure Modes in LIN/K-Line Operation

In the LIN specification a special behavior of the interface is required for some failure conditions. This behavior is also active if a K-Line node is used.

### 11.2.1 Performance in Non Operation Supply Voltage Range

For supply voltages out of operation range the interface may still operate, but communication is not guaranteed. For *LINTX* = 'high' (recessive) the interface shall not drive *LINIO* to dominant state and if *LINIO* is in recessive state the *LINRX* output shall provide a 'high' (recessive).

### 11.2.2 Loss of Supply Voltage and GND Connection

During loss of supply voltage or GND connection the interface shall not interfere with the communication of other LIN nodes. Upon return of connection, normal operation shall resume without any intervention on the LIN bus line (pin *LINIO*).

### 11.2.3 Bus Wiring Short to Battery or GND

The LIN interface is protected against short to battery or short to GND. Upon remove of the fault, normal operation shall resume without any intervention on the LIN bus line (pin *LINIO*).

### 11.2.4 TX Time Out

The TX time out function is implemented to prevent the bus line from being blocked by a permanent 'low' at the pin *LINTX* caused by an error at the ECU or the micro controller. If the *LINTX* signal is 'low' (dominant) for  $t > t_{\text{timeout}}$  the transmission of the *LINTX* signal to the bus is deactivated and the LIN output stage is disabled.

The transmission is reactivated, after a rising edge at *LINTX* was detected. The implemented time out feature requires a minimum data rate of 1600 bit/s.

The time out function can be disabled with the configuration bit **LINTOE** in the configuration register **ComConfig1**.

### 11.2.5 Over Temperature Protection

The LIN bus output *LINIO* is protected against overload with an over temperature protection. In case of over temperature the output transistor is switched off and the diagnosis bit **LINOT** in the diagnosis register **ComDiag** is set. The configuration register is not changed.

### 11.3 Electrical Characteristics LIN

**Table 39 Electrical Characteristics: LIN**

$V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_j=-40$  to  $150^\circ C$ , all voltages with respect to ground, positive current flowing into pin (unless otherwise specified)

## 12 High Speed Controller Area Network (CAN) Transceiver

The Controller Area Network (CAN) is a serial bus system that connects micro controller, sensors and actuators for real-time control applications.

The integrated CAN interface provides the physical layer of the CAN according to ISO 11898. It is suitable for high speed differential data transmission and reception. It works as an interface between the CAN protocol controller and the physical bus lines.

Remote wake up function with a dominant signal at the bus lines is implemented.

### 12.1 Functional Description

The high speed CAN is a two wire differential network which allows data transmission rates up to 1Mbit/s. The input *CANTX* and the output *CANRX* are connected to the micro controller of the ECU. As shown in **Figure 51**, the CAN has a receive unit and a output driver stage, allowing the transceiver to send data to the bus line and monitor data from the bus lines at the same time. It converts the serial data stream available at the transmit data input *CANTX* into a differential output signal at *CANH* and *CANL*. The receiver stage monitors *CANH* and *CANL* and converts the differential voltage to a serial data stream at *CANRX*.

The supply of the CAN transceiver is done out of *V5VCAN*, the wake receiver is supplied out of *V5VSTBY*. The pin *V5VCAN* must be connected directly to the 5V supply pin *V5V*. In order to optimize EMC performance a ceramic capacitor *C<sub>V5VCAN</sub>* should be connected to the pins *V5VCAN* and *PGND* (pin 50).

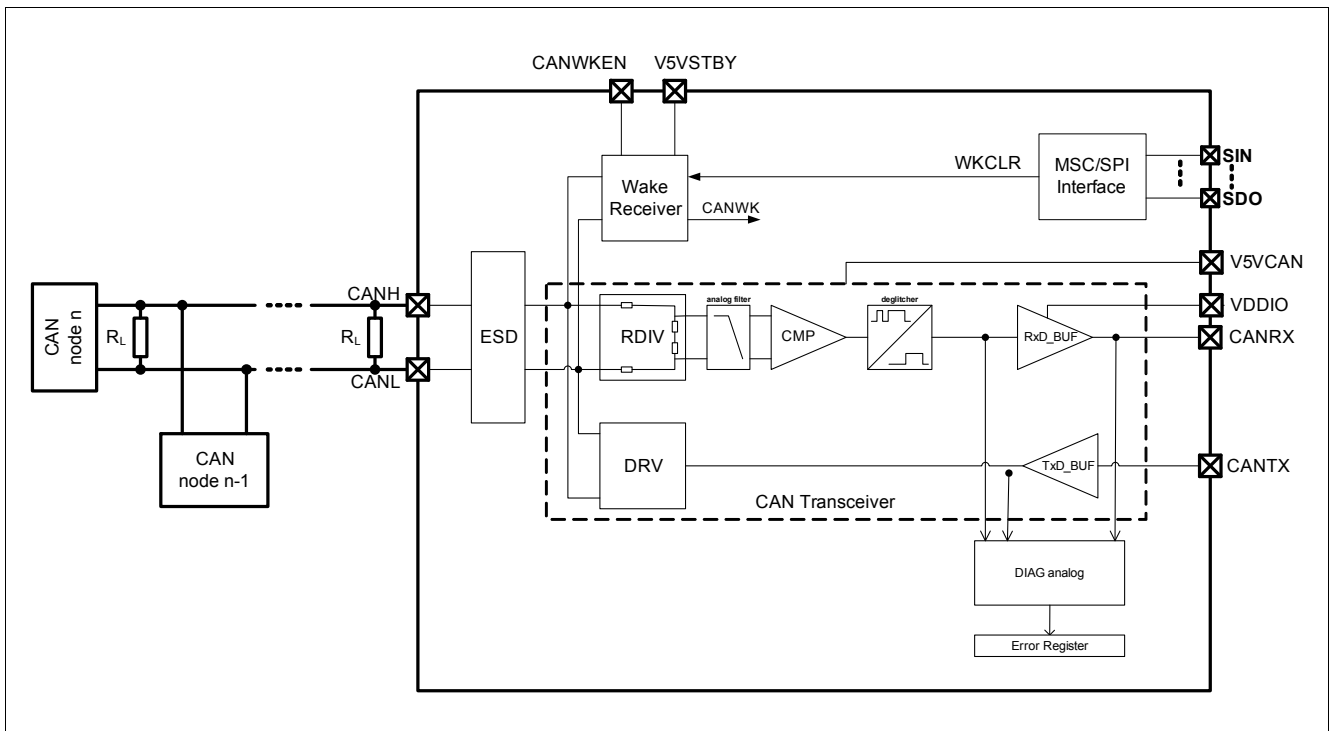

Figure 51 High speed CAN topology

### 12.2 Operation Modes

Four different operation modes are available. Regardless of the supply status the CAN interface does not disturb the communication on the bus line.

### 12.2.1 Normal Operation Mode

In normal operation mode the CAN transceiver sends the serial data stream available at the pin *CANTX* to the CAN bus while at the same time the data available at the CAN bus is monitored at the *CANRX* pin. In normal operation mode all functions are active:

- The driver output is active and drives data from the *CANTX* pin to the CAN bus.
- The receiver unit is active and provides the data from the CAN bus to the *CANRX* pin.
- The failure detection is active.

### 12.2.2 Receive Only Mode

In the receive only mode the CAN transceiver can still receive data from the bus, but the driver output stage is disabled and therefore no data can be sent to the CAN bus. All other functions are active:

- The driver output is disabled and data which is available at the *CANTX* pin will be blocked and not communicated to the CAN bus.
- The receiver unit is active and provides the data from the CAN bus to the *CANRX* pin.
- The failure detection is active.

### 12.2.3 Power Down Mode

If the TLE8888-1QK is not supplied the bus communication is not allowed to be disturbed. Therefore the resistors of the receiver unit are switched off and the bus input pins *CANH* and *CANL* are high resistive.

### 12.2.4 Remote Wake Up

The wake receiver is internally supplied from the standby supply pin *V5VSTBY*. The wake up function is enabled by an external connection of the pin *CANWKEN* to the standby supply pin *V5VSTBY*. The wake function is disabled by an external connection to *AGND* and the current consumption of the wake up circuit is reduced to leakage currents only.

In “ECU Sleep” state a dominant signal at *CANH* and *CANL* for longer than the **CAN Wake up filter time** preceded by a recessive signal causes an internal wake up and the internal wake signal **CANWK** is set. With a wake clear command (set bit **WKCLR** to “1” in command register **Cmd0**) **CANWK** is reset (status see bit **CANWK** in the status register **OpStat0**). The next wake up is only detected with a transition from recessive to dominant. With this implementation of the wake up procedure, bus line dominant clamping does not lead to permanent wake up.

In **Figure 52**, **Figure 53** and **Figure 54** the behavior is shown.

High Speed Controller Area Network (CAN) Transceiver

Figure 52 CAN Remote Wake Up

Figure 53 CAN Wake Up State machine

**Figure 54 State Transitions at CAN Remote Wake Up**

## 12.3 Diagnostic Functions

The CAN transceiver has an implemented diagnostic unit. Bus failures and local failures can be detected.

### 12.3.1 CAN Bus Failure Detection

In normal operation the CAN transceiver can detect following bus failure:

- Bus line dominant clamping (bit **CANBDC** in diagnosis register **ComDiag**)

Following bus failures can't be detected (outputs are protected):

- CANH shorted to GND
- CANL shorted to GND
- CANH shorted to low voltage supply
- CANL shorted to low voltage supply
- CANH shorted to  $V_{Bat}$
- CANL shorted to  $V_{Bat}$
- CANH open
- CANL open
- CANH shorted to CANL

### 12.3.2 Local Failure Detection

In normal operation the CAN transceiver can detect following local failures:

- CAN TX dominant time-out (bit **CANTXTO** in diagnosis register **ComDiag**)
- Over temperature (bit **CANOT** in diagnosis register **ComDiag**)

In case of failure detection only the corresponding diagnosis register bits are changed. No change in the configuration occurs.

## 12.4 Electrical Characteristics CAN Transceiver

## 13 Micro Second Channel MSC

The bidirectional micro second channel (MSC) is a serial interface which is especially optimized to connect peripheral devices via serial link to micro controller. The serial communication link is built up by a fast synchronous downstream channel from micro controller to the device and an asynchronous upstream channel (referenced to downstream clock). The downstream interface can be “low voltage differential” (*FCLN*, *FCLP*, *SIN*, *SIP*, *CSN*) or “single ended” (*FCLP*, *SIP*, *CSN*).

Via MSC, the micro controller controls the outputs and logic of the device including the diagnosis and monitoring module. Read data is requested by micro controller via downstream communication and returned by the device via MSC upstream channel.

Multiple “power devices” with MSC for downstream operation are possible. The device is selected by *CSN*. The MSC logic is internally supplied and referenced to *AGND*.

The behavior of the MSC interface during reset is described in [Table 6](#) and [Table 7](#) in [Chapter 5.2](#).

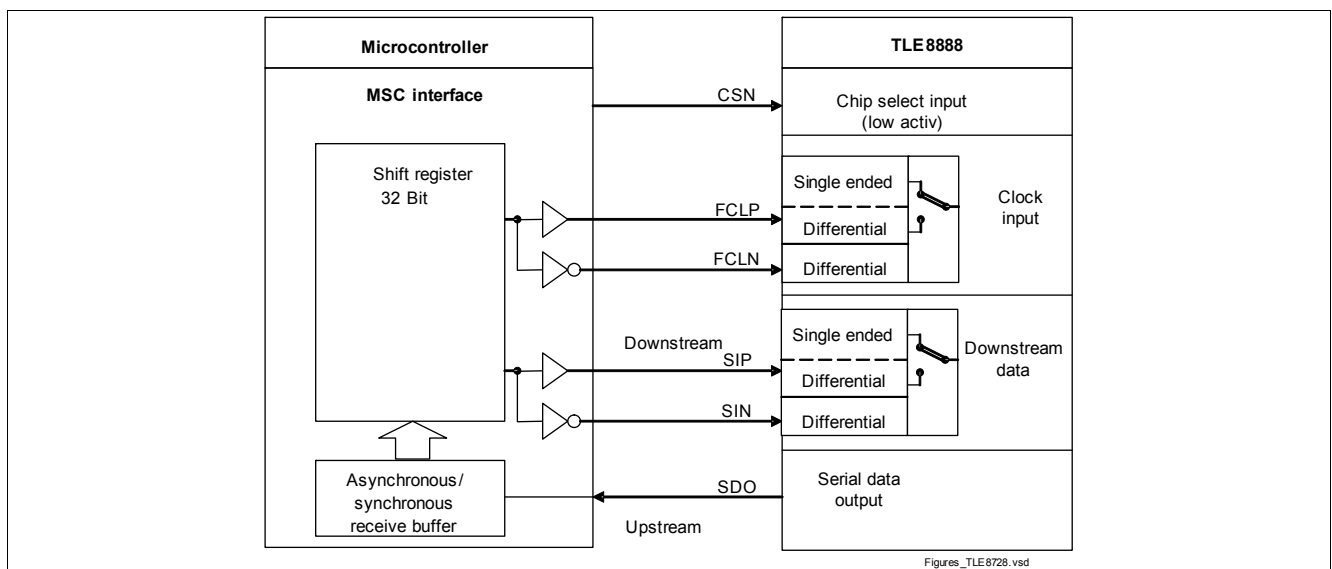

Figure 55 MSC Interface (not tested, overview only)

### 13.1 Downstream Communication

Downstream frames are synchronous serial frames with clock and data line.

The physical interface for downstream communication can be “low voltage differential” or “single ended” type. Both interface types are using individual pins (*FCLN*, *FCLP*, *SIN* and *SIP*) and common pins (*CSN* and *SDO*). For single ended interface *FCLN* and *SIN* have to be connected to *VDDIO*. For low voltage differential interface both input voltage levels must be within the defined input voltage range.

The frames and the behavior of the communication are the same in differential and single ended mode. Differential inputs for downstream data are *SIP* and *SIN*; the differential input signal *SIP* – *SIN* is the same logical signal as *SIP* alone in single ended mode and SI will be used in the description for both types of communication. The clock pins are *FCLP* and *FCLN*, the differential clock *FCLP* – *FCLN* is the same logical signal as *FCLP* in single ended mode and CLK will be used in the description for both types of communication.

There is one input *CSN* for chip select, and one output *SDO* for upstream data. The device is always the slave in this communication link.

The *CSN* signal enables receiver circuits automatically during a downstream frame transmission.

Two types of downstream frames are defined:

- Command frames (selection bit =“1”)
- Data frames (selection bit =“0”)

The device MSC uses non inverting polarity for SI and CLK: SI changes its state with the rising edge of CLK and is sampled with the falling edge; a logic ‘1’ is a ‘high level’ on SI, and a logic ‘0’ is a ‘low level’ on SI. Data at SI is latched by the device on the falling edge of CLK.

The *CSN* input is active low during the active phases of command or data frames. An active enable signal validates the SI input signal. Outside the active phase (*CSN* line is at high level) data at SI is ignored.

It is possible to drive multiple “power devices” with shared CLK and SI lines and individual *CSN* signal.

Command frames and data frames may be sent in any sequence (with a passive phase of at least 2 CLK-cycles after each frame).

**Table 41 Execution of commands**

Event on MSC downstream	upstream busy	upstream idle
valid read command frame	ignored	executed
valid write command frame	executed <sup>1)</sup>	executed
valid data frame	accepted	accepted
invalid command	ignored	ignored
invalid data frame	ignored	ignored

1) only after  $t_{prep,sr}$  or  $t_{prep,mr}$ , see also [Chapter 13.2](#)

The serial clock CLK must be active (toggling) during upstream communication even when no command frame or data frame is transmitted.

The clock period of CLK is defined as  $t_{FCL}$ , maximum downstream clock rate is  $f_{FCLmax}$ .

The active phase of a downstream frame starts with the falling edge of the signal on *CSN* and ends with the rising edge. *CSN* changes its state with the rising edge of clock CLK.

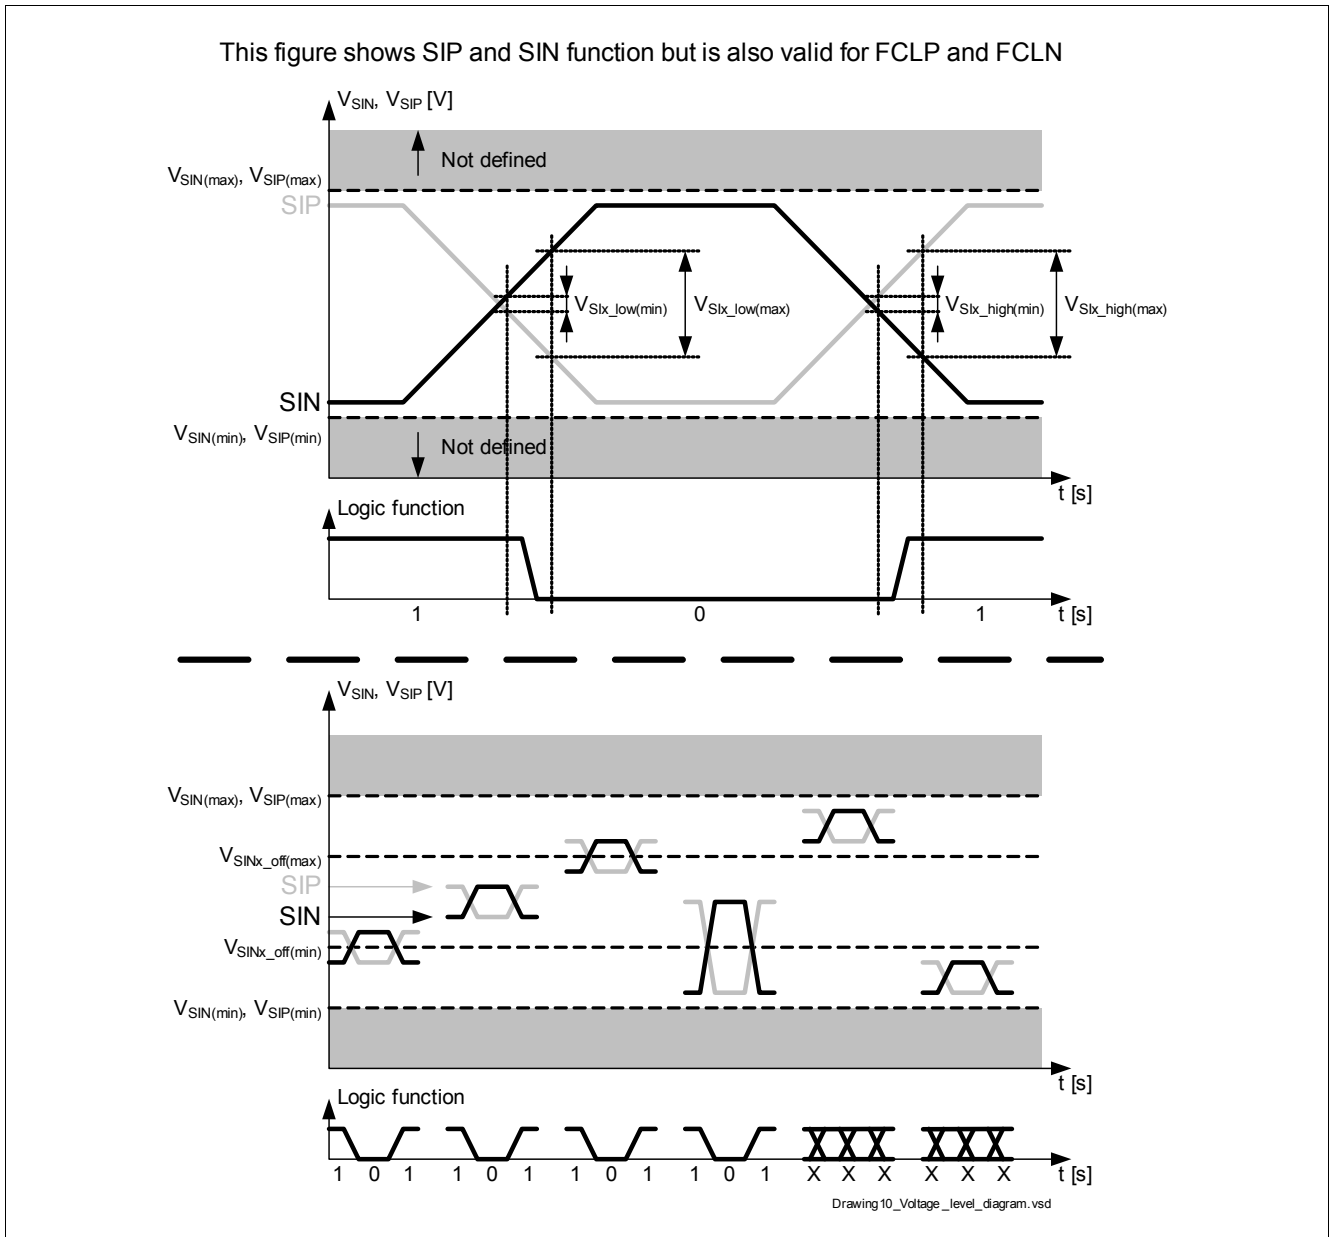

Figure 56 Voltage level diagram

### 13.1.1 Downstream Supervisory Functions

A command- or data frame is interpreted as valid, if it has the correct number of CLK pulses (a frame has a length of 17 clock pulses). Clock pulses are counted at the falling edge of the signal.

There is no parity check.

If TLE8888-1QK receives no valid data frame for  $t > t_{MSC\_mon}$ , the device switches off the output stages (all output stage control bits are set to “0”), the bits **01E** to **024E** in the configuration registers **OEConfig0** to **OEConfig3** are set to “0” and the MSC time out failure bit in the register **ComDiag** is set to “1”. The MSC time out failure bit is reset by a readout of the register **ComDiag** and all output stages remain off. For switching on the stages the bits **01E** to **024E** in the configuration registers **OEConfig0** to **OEConfig3** must be set to “1” and the control bits must be set. Outputs which are configured to be driven directly with the direct drive inputs are switched according the input level of the pins **INI** to **INI2** after set of the bits **01E** to **024E**.

### 13.1.2 Command Frame

A command frame always starts with a high level bit (command selection bit). The number of command bits of the active phase of a command frame is fixed to 16. A command is executed only if the number of transmitted bits of an active command frame is equal to 17.

The length of the command frame's passive phase  $t_{CPP}$  must be a minimum of  $2 * t_{FCL}$  (2 clock pulses).

Alternatively the passive phase can consist in  $t_{CPP} = t_{FCL}$  (1 clock pulse) followed by a frame of wrong length (4...8 bits, with or without *CSN* active low) and a second  $t_{CPP} = t_{FCL}$  (1 clock pulse).

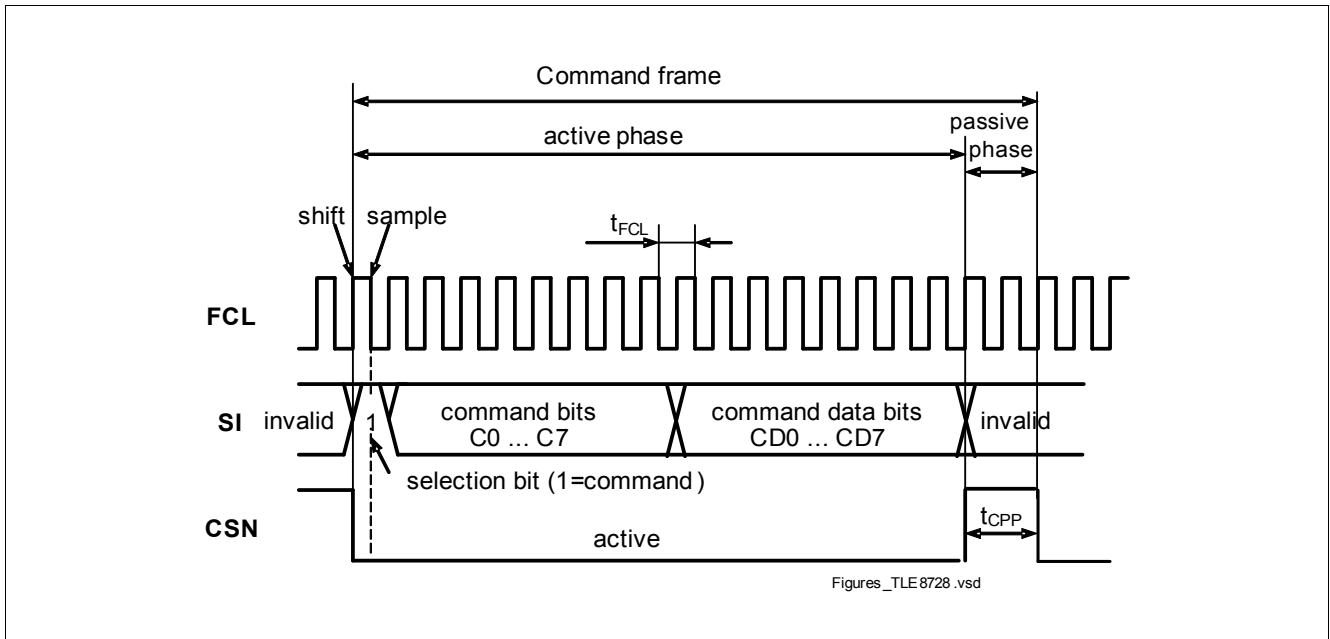

Figure 57 MSC command frame

Content of a command frame (LSB transmitted first)

Table 42 Command frame

Bit #	Description
0 (first bit)	= '1': command selection bit
1...8	Command [C0 ... C7]
9...16	Data for the command [CD0 ... CD7]

The least significant (LSB) bit of a command is transmitted first

### 13.1.3 Data Frame

A data frame always starts with a low level bit (data selection bit). The number of the data bits of the active phase of a data frame is fixed to 28 bit.

A data frame is accepted if the actual length is the expected length 29.

MSC Monitoring  $t_{MSC\_mon}$  is re triggered by any data frame with correct length (no other error detection mechanism is implemented).

The length of the data frame's passive phase  $t_{DPP}$  must be a minimum of  $2 * t_{FCL}$  (2 clock pulses).

26	O3ON <sup>1)</sup>
27	IGN4ON <sup>1)</sup>
28	O12ON <sup>1)</sup>

1) Definition see [Chapter 14.6](#).

There is no parity bit in the data frame.

The data is stored in the control register [Cont0](#) to [Cont3](#).

### 13.2 Upstream Communication

The serial data output *SDO* is the synchronous serial data signal of the upstream channel and is always single ended. The polarity is ‘non inverting polarity’– i.e. a low level bit at *SDO* is stored in the micro controller as a logic ‘0’, and a high level bit at *SDO* is stored in the micro controller as a logic ‘1’. The frequency for *SDO* is derived from CLK by an internal divider and can be configured via MSC.

The output of *SDO* can be configured as an open drain or an push pull output. The set is done with the bit [MSCO](#) in the configuration register [ComConfig0](#). The full range of up stream frequency divider settings in the configuration register [ComConfig0](#) bits [MSCF](#) is valid for the push pull output configuration.

**Figure 59** MSC upstream communication (not tested, overview only, Single Ended)

The data frame could be defined with 12 and 16 bit according the setting of [MSCUF](#) in the configuration register [ComConfig0](#). In [Figure 60](#) the formats are shown. The address bits A2 and A3 are used for the selection of the upstream data register in the micro controller.

**Definition of Address Bits A0 to A3 in 16 Bit Upstream Mode:**

- **Fixed A0 to A3 Value:**  
The value of the address bits A0 to A3 is fixed according the definition of [MSCA](#) in the configuration register [ComConfig1](#) at the rising edge of *CSN* of the read command. For read out with multiple read out commands the value of A0 to A3 does not change.
- **Multiple Read Command Mode:**  
This mode is especially for the multiple read commands and the configuration of the micro controller in UD3 interrupt mode. A2 and A3 are used in this mode to define the upstream data register (UD0 -UD3) and a number of n times 4 of upstream frames. A0 is defined as read overflow and A1 is defined as read busy.

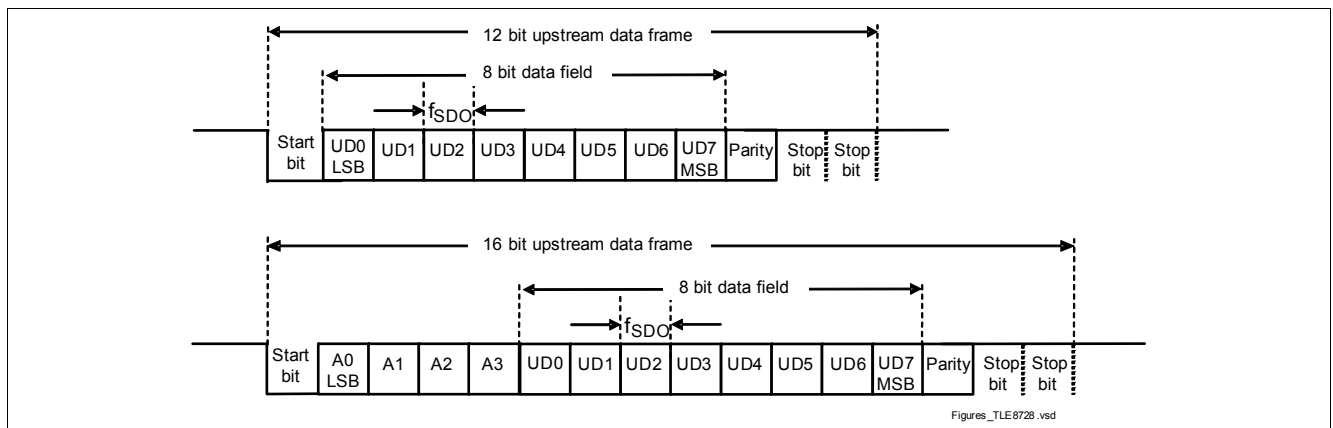

**Table 44 Definition of A0 in Multiple Read Command Mode for 16 Bit Upstream Format**

A0	Description
0	No read command is ignored
1	A read command was sent during upstream communication. This read command was ignored and this is signaled with A0=1

**Table 45 Definition of A1 in Multiple Read Command Mode for 16 Bit Upstream Format**

A1	Description
0	last upstream frame; after finish of this frame next transmitted read command will be executed
1	Upstream activities required by an multiple read commands are ongoing

**Figure 60 MSC upstream frame**

**Table 46 12 Bit Upstream Frame**

Bit	description
0	start bit, always '0'
1-8	upstream data bits UD0..7
9	parity bit (The parity bit is set in order to achieve an even number of '1' in Bits UD0..7+Parity)
10, 11	stop bits, always '1'

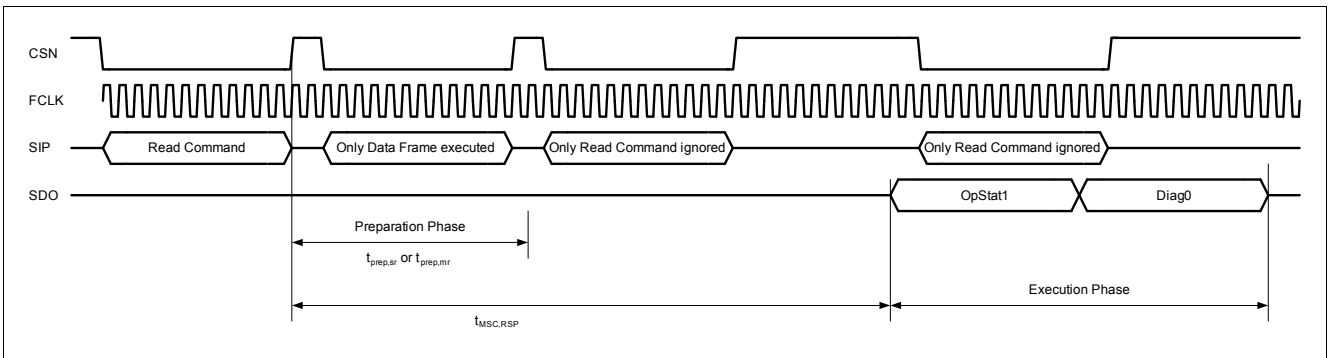

**Table 47 16 Bit Upstream Frame**

Bit	description
0	start bit, always '0'
1-4	address bits A0..3

**Table 47 16 Bit Upstream Frame (cont'd)**

Bit	description
5-12	upstream data bits UD0..7
9	parity bit (The parity bit is set in order to achieve an even number of '1' in Bits UD0..7+Parity)
10, 11	stop bits, always '1'

Transmission of the registers via upstream starts within  $t_{MSC\_RSP}$  after read command has been received. During an ongoing upstream communication the device will ignore further read commands until the upstream data transfer is finished. A new read command is accepted if the rising edge  $CSN$  arrives after the last stop bit has been sent. Data frames are executed independently of ongoing read requests. Write commands are ignored during **MSC upstream preparation time for single read command  $t_{prep,sr}$**  or **MSC upstream preparation time for multi read command  $t_{prep,mr}$**  (see Figure 62). After that time the write commands are executed also during ongoing upstream communication. If the write command is changing the register which is in transmission, the old register content will be sent. With setting the command bit **MSCUPS** in the command register **Cmd0** the running upstream transmission is stopped and all remaining read request of a multiple read command are cleared.

**Figure 62 Example MSC upstream and active downstream communication**

### 13.3 Timing Characteristics

**Figure 63 MSC timing**

The downstream clock within the device must be active during an upstream data frame transmission (i.e. each answer to a READ command).

The upstream response time  $t_{MSC\_RSP}$  describes the time between end of read command (rising edge of  $CSN$ ) to beginning of up-stream communication (falling edge of start bit).

### 13.4 Electrical Characteristics

**Table 48 Electrical Characteristics: Micro Second Channel**

1) not subject to production test, specified by design

2) Application must ensure that current into this pin does not exceed this value.

3) See [Figure 57](#), [Figure 58](#) and [Figure 63](#)

## 14 Register and Commands

In [Chapter 14.1](#) to [Chapter 14.6](#) detailed descriptions and definitions of the registers and commands are shown. General definition for all registers and commands are described below.

### Offset Address

The offset address used for the register address is mapped to the command bits from C1 to C7. In [Figure 64](#) an example is shown. Maximum allowed address is 7F<sub>H</sub>.

**Figure 64 Mapping Offset Address to the Command Bits**

### Read Access

A read access to a register is done by sending a “0” for the bit C0 of the command frame of the MSC or the SPI frame. All register bits are updated constantly. With the positive edge of *CSN* of a valid read command the internal register information is loaded into the output shift register. The communication via *SDO* to the micro controller is according to the serial interface mode MSC or SPI. Therefore the read information is related to the time of the positive edge of *CSN*.

### Write Access

A write access to a register is done by sending a “1” for the bit C0 of the command frame of the MSC or the SPI frame or with the data frame of the MSC communication. With the positive edge of *CSN* of a valid write access for read/write register the bits are set and for command registers the defined function is executed (e.g. multiple read command).

### Command Register

These registers are write only registers. Following functions are executed:

- **Main relay switching with bits *MRON* and *MRSE* in command register *Cmd0***: In all states where a serial communication with the TLE8888-1QK is allowed the main relay can be switched. This is done by enabling the command with a “1” for *MRSE* and a “0” for switch off or a “1” for switch on for *MRON*. Switch off of the main relay leads for an application with supply of the ECU over the main relay path to a power down.
- **VRS diagnosis start with bit *VDIAGS* in command register *Cmd0***: With a “1” the VRS diagnosis is started. A “0” leads to no action.
- **Stop of a MSC upstream communication with bit *MSCUPS* in command register *Cmd0***: With a “1” the upstream communication is stopped immediately. This leads during an upstream to invalid communication. This command is implemented to stop especially multiple read communication. A “0” leads to no action. For SPI mode this command has no effect.
- **Start of the engine off timer with bit *EOTS* in command register *Cmd0***: With a “1” the engine off timer is started if the configuration is set accordingly. A “0” leads to no action.
- **Restart of the delayed off timer with bit *RDOT* in command register *Cmd0***: With a “1” the delayed off timer is reset and started again. A “0” leads to no action.

- **Wake up signal clear with bit WKCLR in command register Cmd0:** With a “1” all internal wake up signals (WKINT, CANWK, EOTWK) are reset. A “0” leads to no action.
- **Response write command FWDRspCmd and FWDRspSyncCmd:** With the write access to these registers the 8 bit response byte is sent to the TLE8888-1QK. The interpretation of the sent response byte is done according the description in **Chapter 6**.
- **Multiple read command MSCReadWd0 to MSCReadWd1:** Multiple read commands are only allowed for MSC setup of the serial interface. The number of read register is defined by a “1” in the data bits of the command. The chosen register is sent in the order MSB down to LSB (see **Figure 65**). In SPI setup a multiple read command is an invalid communication. During a multi read upstream read commands are ignored, write commands are allowed. To stop an upstream operation use the command **MSCUPS**.
- **Software reset command CmdSR:** With the execution of this command the software reset of the TLE8888-1QK is performed according **Table 7** in **Chapter 5**.
- **Central output enable command CmdOE:** With the execution of this command the central output enable bit is set or reset. For the description of the functionality see **Chapter 9.2**. The status of the central enable bit is available in register **OpStat1**.
- **Lock command CmdLOCK:** With the execution of this command the lock bit is set or reset. This bit is used to lock some configuration registers (see **Table 50**) to avoid a change of these register e.g. during operation. The status of the lock bit is available in register **OpStat1**.

Figure 65 Example of a Multi read Command

### Diagnosis Register

The diagnosis register bits are set according the asynchronous detection circuits. The reset of the diagnosis bits is done with the read out of the registers if the failure condition is not detected anymore.

### Central Over-temperature Bit COT in Diagnosis Register Diag0

The central over temperature bit is an OR combination of all over temperature detection signals which leads to active diagnosis bits. With at least one active over-temperature diagnosis the central over-temperature bit is “1”, with no active over-temperature diagnosis this bit is “0”. All other diagnosis signals doesn’t change the status of the central over-temperature bit.

**Central Failure Bit CF in Diagnosis Register Diag0**

The central failure bit is an OR combination of diagnosis bits (see [Table 49](#)). If one or more of these diagnosis bits are active then the central failure bit is “1”. If all are inactive the central failure bit is “0”. The over-temperature diagnosis doesn’t change the status of the central failure bit.

**Table 49 Overview of Diagnosis Registers an Bits affecting the Central Failure Bit**

Register	Offset	Bit(s)	Note
ComDiag	024 <sub>H</sub>	MSCTO, COMFE, CANBDC, CANTXTO	
OutDiag0 to OutDiag4	026 <sub>H</sub> to 029 <sub>H</sub>	all bits	central failure bit not set if only over-temperature is detected
PPOVDiag	02A <sub>H</sub>	all bits	
BriDiag0	02B <sub>H</sub>	all bits	
BriDiag1	02C <sub>H</sub>	only over-current bits	
IgnDiag	02D <sub>H</sub>	all bits	
WdDiag	02E <sub>H</sub>	WWDTO, WWDSCE, FWDREL, FWDREA	

**Engine Off Timer Register EOTStat0 to EOTStat2, EOTConfig0 and EOTConfig1**

These register are located in the standby block and are supplied by the standby supply. They are not reset with the power on reset of the digital block.

## 15 SPI

Alternatively to the MSC communication interface a SPI interface is available. It uses the pins *SIP*, *SDO*, *CSN* and *FCLP*. The configuration is done via the pins *FCLN* and *SIN*. *FCLN* must be connected to *VDDIO* and *SIN* must be connected to *AGND*. In SPI mode the output stage of the pin *SDO* is set to push pull operation (definition and description see [Chapter 13.2](#) and [Chapter 13.4](#)).

The definition of the registers is the same as for the MSC communication (see [Chapter 14](#)), only the frame is SPI specific (see [Figure 67](#) and [Chapter 15.1](#)). Multiple read commands are not allowed.

There is no monitoring of valid transmissions implemented (like MSC monitoring, see [Chapter 13.1.1](#)).

Figure 66 Block diagram of the SPI interface

### 15.1 SPI Protocol

The principle of the SPI communication is shown in [Figure 67](#). The message from the micro controller must be sent LSB first. The data from the *SDO* pin is sent LSB first. The TLE8888-1QK samples data from the *SIP* pin on the falling edge of *FCLP* and shifts data out of the *SDO* pin on the rising edge of *FCLP*. Each access must be terminated by a rising edge of *CSN*.

All SPI messages must be exactly 16-bits long, otherwise the SPI message is discarded and the bit **COMFE** in diagnosis register **ComDiag** is set to "1".

There is one message delay in the response to each message (i.e. the response for message N will be returned during message N+1).

There are two valid access possible:

- Write access to registers with write permission: the answer is 1 for the  $\overline{R/W}$  bit, the address and the content of the register
- Read access to register with read permission: the answer is 0 for the  $\overline{R/W}$  bit, the address and the content of the register

Everything else is not executed.

*Note: Write access to multiple read commands are also not valid in SPI mode.*

Status Flag Indication: after the falling edge of *CSN* and before the first rising edge of *FCLP* the level of the *SDO* indicates an OR combination of the status of the central failure bit **CF** and the central overtemperature bit **COT** of the diagnosis register **Diag0**.

With this feature during every SPI communication a check of the diagnosis status can be done without additional read access of the diagnosis register.

**Figure 67 SPI Protocol**

SPI Answers:

- during power on reset: SPI commands are ignored, *SDO* is always tristate
- after power on reset: the address and the content of the status register **OpStat0** is transmitted with the next SPI transmission
- during watchdog reset: SPI commands are ignored, *SDO* has the value of the status flag
- after watchdog reset: the address and the content of the diagnosis register **FWDStat1** is transmitted with the first SPI transmission after the low to high transition of *RST*
- after a read or write command: the address and content of the selected register is transmitted with the next SPI transmission (for not existing addresses or wrong access mode the data is always “0”)
- after an invalid communication frame: the address and the content of the diagnosis register **Diag0** is transmitted with the next SPI transmission and the bit **COMFE** in diagnosis register **ComDiag** is set to “1”

## 15.2 SPI Frame Definition

### Overview SPI Frame

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CD7	CD6	CD5	CD4	CD3	CD2	CD1	CD0	C7	C6	C5	C4	C3	C2	C1	C0

Field	Bits	Type	Description
C0	0		$\overline{\text{R/W}}$ Bit: defines the access to the register
C[7:1]	[7:1]		Address Bits, definition see <a href="#">Chapter 14</a>
CD[7:0]	[15:8]		Data Bits, definition see <a href="#">Chapter 14</a>

### 15.3 Electrical Characteristics SPI

**Table 51 Electrical Characteristics Communication**

$V_S=13.5V$ ,  $V_{V5V}=5V$ ,  $T_j=-40$  to  $150^\circ C$ , all voltages with respect to GND, positive current flowing into pin, (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note / Test Condition	Number
		Min.	Typ.	Max.			
SPI detection threshold for <i>SIN</i>	$V_{FCLN\_SPI}$	0.3	–	0.7	V		P_15.1
Single ended mode detection threshold for <i>FCLN</i>	$V_{FCLN\_single}$	2	–	3	V		P_15.2
<i>SDO</i>						see <a href="#">Chapter 13.4</a>	P_15.3
Input low level ( <i>SIP</i> , <i>FCLP</i> , <i>CSN</i> )	$V_{INn\_L}$	-0.3	–	0.8	V		P_15.4
Input high level ( <i>SIP</i> , <i>FCLP</i> , <i>CSN</i> )	$V_{INn\_H}$	1.6	–	5.5	V		P_15.5
Input hysteresis ( <i>SIP</i> , <i>FCLP</i> , <i>CSN</i> )	$V_{INn\_Hys}$	0.1	–	0.5	V		P_15.6
Clock frequency	$f_{SPI}$	–	–	5	MHz		P_15.7

## 16 EMC Requirements

### 16.1 ISO Pulse Tests

Definitions for all ISO pulse test on application including the TLE8888-1QK are regarding standard ISO 7637-2:2011. Following amplitude definition for the tests are required:

- Pulse 3a: VS= -140V, all outputs available on ECU connector
- Pulse 3b: VS= 140V, all outputs available on ECU connector
- Pulse 5: VS= +38.5V (clamped), td=400ms (ECU reset is permitted under this test, outputs will be switched off)

The tests are performed only on application level.

## 17 Application Information

Note: The information in this chapter is given as a hint for the implementation of the device only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

Note: These are very simplified examples of application circuits. The functions must be verified in the real application.

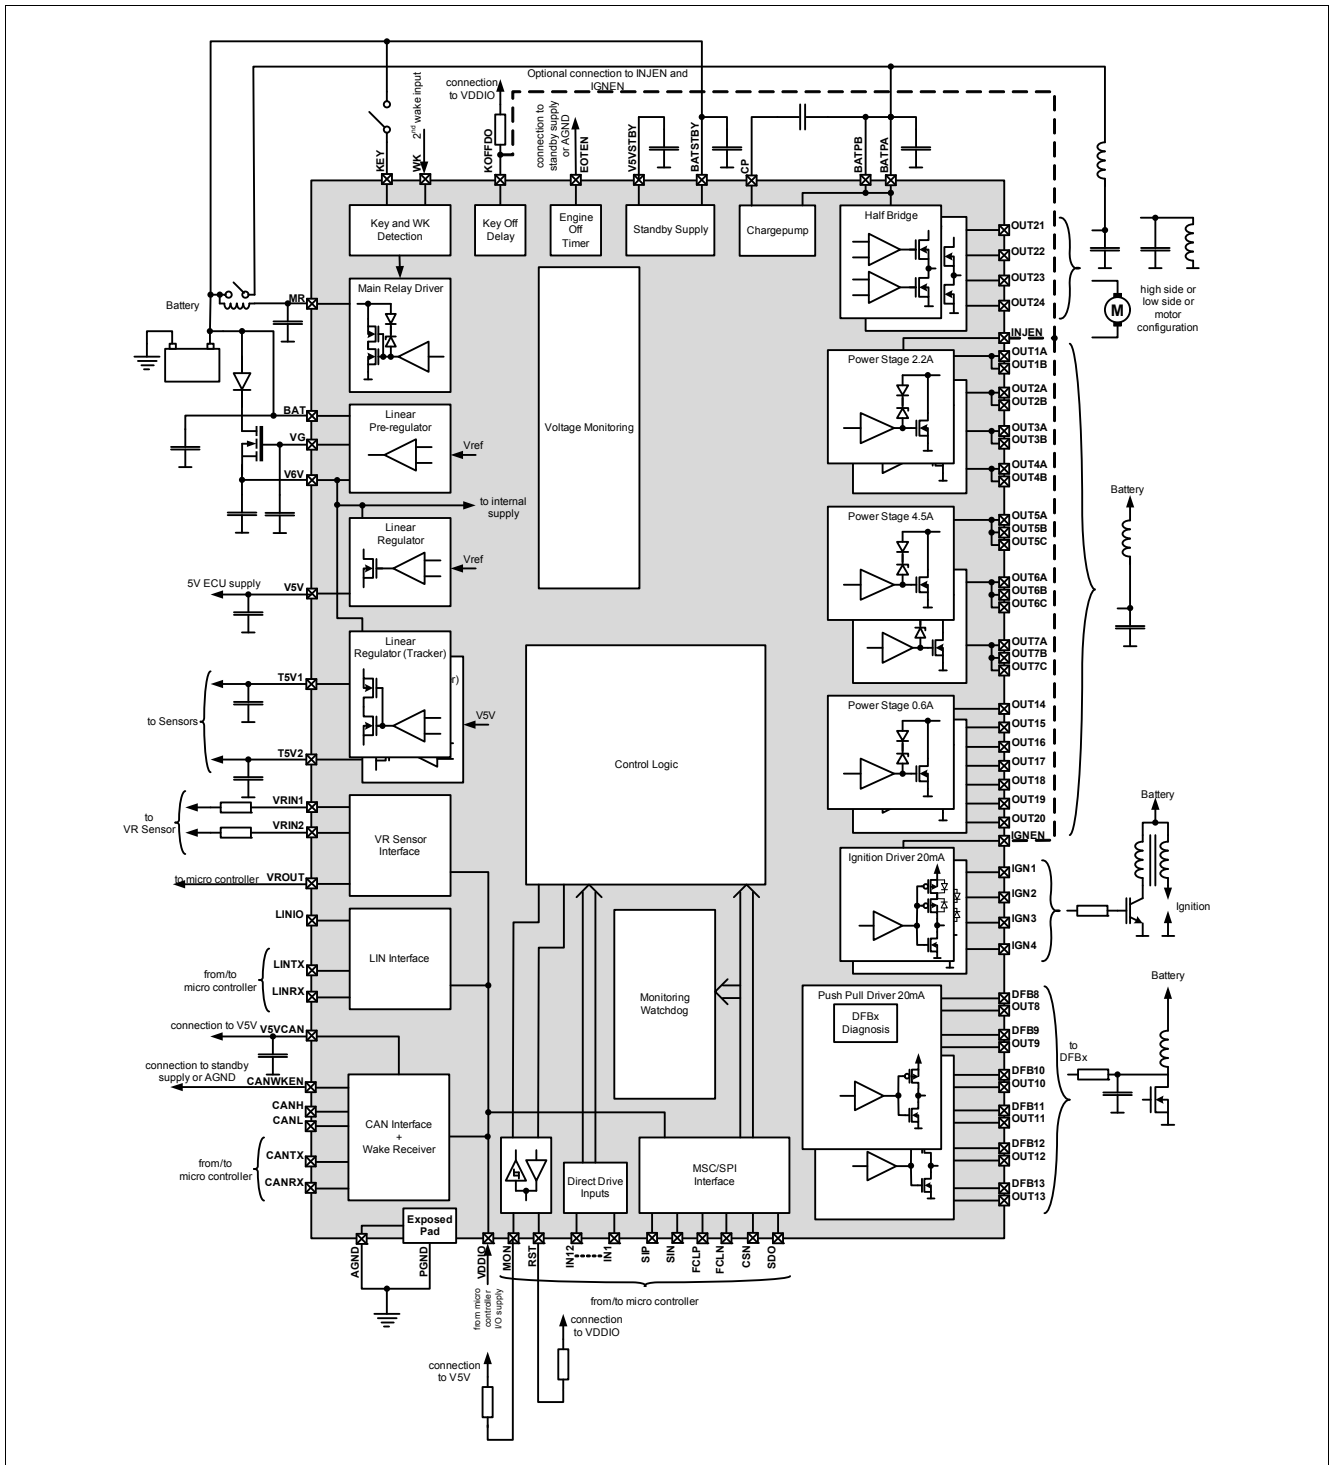

Figure 68 Application Diagram

### 17.1 Supply Systems

**Figure 69 Application Diagram Supply Systems**

In **Figure 69** three setups for connecting the battery supply to the TLE8888-1QK are shown. With non permanent battery supply there is no standby supply available and all functions related to this supply (e.g. engine off timer) are not active. Wake up could be done by a signal at the pins *KEY* and *WK*.

In a permanent supply system the standby supply is permanently connected to the battery and all functions related to this supply can be enabled (e.g. CAN remote wake up). The pins *BATPA* and *BATPB* must be connected to the switched battery supply because there is no special mode to reduce the current consumption in standby mode. The pin *BAT* and the external MOSFET of the pre regulator are allowed to be connected permanently to the battery.

### 17.2 VR Sensor Interface

For Hall sensor signal detection in [Figure 70](#) and [Figure 71](#) different proposals for the external devices are shown. For the description of the set ups see [Chapter 10](#)

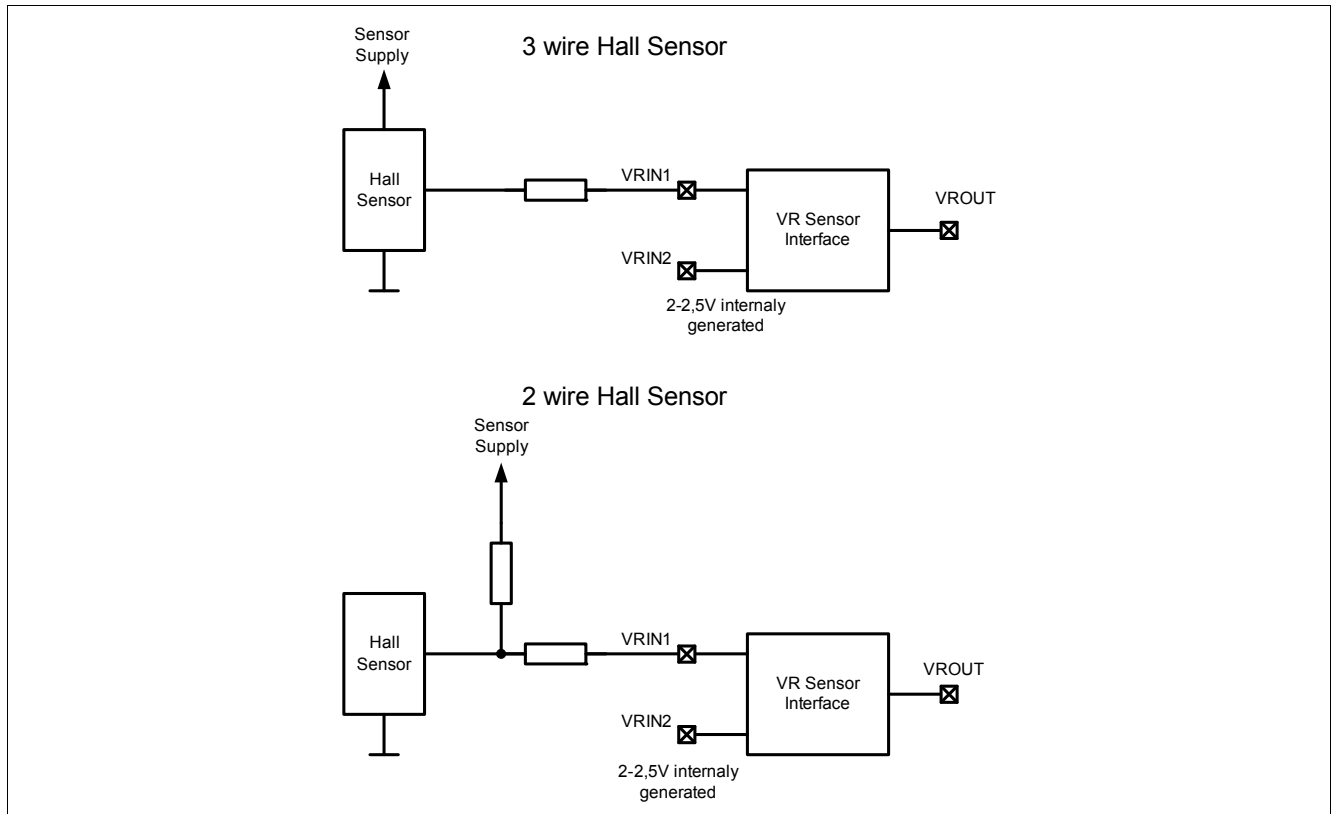

Figure 70 Application Circuit for VR Sensor Interface used for Hall Sensor in Hall Mode Set Up

**Figure 71 Application Circuit for VR Sensor Interface used for Hall Sensor in Auto, Semi Auto and Manual Detection Mode Set Up**

18 Package Outlines

Figure 72 LQFP-100

For the LQFP-100 package the lead frame version C66065-A6837-C029 with an exposed pad size of 8.5mm\*8.5mm is used.

**Green Product (RoHS compliant)**

To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).

## 19 Revision History

Revision	Date	Changes
V1.1	2014-08-20	on all pages: general name changed to "TLE8888-1QK" and date and revision
V1.1	2014-08-20	page 5 and 6: 2 device types added
V1.1	2014-08-20	page 29: parameter P_5.3.24 min/max changed
V1.1	2014-08-20	page 52: parameter P_7.5.2 and P_7.5.11 max defined
V1.1	2014-08-20	page 57: parameter P_8.8.38, P_8.8.39, P_8.8.40, P_8.8.42, P_8.8.43 and P_8.8.44 definiton improved
V1.1	2014-08-20	page 58: parameter P_8.8.45 definiton improved
V1.1	2014-08-20	page 62: table 25 corrected
V1.1	2014-08-20	page 100: PGND reference pin changed
V1.1	2014-08-20	page 2, 9, 10, 11, 17, 18, 20, 21, 22, 26, 38, 39, 43, 44, 45, 48, 49, 52, 56, 58, 196: missing variable names added
V1.0	2014-03-13	Data Sheet

### **Legal Disclaimer**

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

### **Information**

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office ([www.infineon.com](http://www.infineon.com)).

### **Warnings**

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.

Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.
